ANATOMIC STRUCTURE AND FUNCTION*

W. OPHÜLS, M.D.

SAN FRANCISCO

Work well done along any line of human endeavor is a satisfaction and a reward in itself. Still it behooves us to pause once in a while in the press of our labors in order to ascertain whether the direction which we are following is the correct one, whether there is promise of progress commensurate to the effort employed or whether a shifting of the point of attack or a change of the means employed may not give better result. This seems to apply with special force to pathology at the present moment, when we hear such warnings as that addressed to us by Yandell Henderson, who, in 1911, stated before this section that "a man trained by autopsy and microscope is inevitably a morphologist. Just in proportion as he is fitted to deal with morphologic processes he is unfitted to handle and expound functions of a physical nature—unless, of course, he happens to be an all-around genius," or when we hear the repeated admonition of such men as Meltzer to pay less attention to morphologic problems and more to functional studies. If Henderson's assertion is at all correct, present conditions are truly deplorable, because many men have been and still are being trained by necropsy and microscope and if this study unfits them to understand function in its proper light, the sooner all efforts in this direction cease the better, because I cannot conceive of any object in morphologic research except as a help to the clearer understanding of function.

The question of the relation of structure to function is the great biologic problem, if we take structure in its broadest sense as including the structure of the chemical substances which make up the living protoplasm. In the last resort our interpretation of the relation of structure to function will rest on our conception of the relation of force to matter, and, as I believe we are all agreed that these two expressions designate merely two human ways of looking at the same thing, we might come to the conclusion that the whole discussion is idle and entirely futile. I do believe that this identity, if I may say so, of structure and function is sometimes lost sight of to the detriment of scientific reasoning, although nature, if we only look at it with open eyes, constantly reminds us of this fact, no more commonly perhaps than in the

field of pathology. Looking at the question from this broadest point of view it does not require much of an argument, for instance, to convince us that function determines structure just as in its turn structure determines, delimits—that is, places definite limits on function. Still, what we grant theoretically, must be worked out practically. It is with the practical imperfection of our knowledge that we are concerned and with the question of how best to improve on it.

Any student of medical history knows how much our knowledge of physiology has advanced with the gradual progress in gross anatomy and how much more many of the intricate problems were clarified by the knowledge of the finer structure of the tissues as revealed by the microscope. Our fundamental conceptions with regard to the cell as the living unit, with regard to cell life and cell activity, could not have been arrived at without the help of the microscope, and on this same solid basis of gross anatomic and histologic knowledge rests modern physiology, and with that pathology.

It is only natural that the splendid advances made by the introduction of the microscope aroused excessive expectations in the minds of some as to what might be accomplished by the use of this instrument. We certainly know now that it has its great limitations so far as power of vision and its applicability to living tissue is concerned; nevertheless, the insight which we have gained by means of it into physiologic and pathologic processes is truly remarkable.

If I may speak from the point of view of a pathologist, the condition of affairs at present seems to be something like this:

There exists quite a large and constantly growing territory in this science in which our knowledge of the gross and microscopic anatomy furnishes a very adequate explanation of the functional disturbances which we observe during life. This is especially true if we include parasitology, gross and microscopic, although here also the limit of usefulness of the microscope is being reached as shown by the experiments with filtrable virus.

It must be emphasized, however, that structural change does not necessarily mean change in function. I believe that in this regard the importance of minute histologic lesions in the tissue has been greatly exaggerated. We must constantly bear in mind, especially in the important glandular organs, the existence of a large amount of reserve tissue which must be eliminated before the function of the organ as a whole will be affected. We also have to take into account the remarkable power of regeneration and of compensatory hypertrophy which these organs possess. Even when we give due consideration to these

* Chairman's address, read before the Section on Pathology and Physiology at the Sixty-Fifth Session of the American Medical Association, Atlantic City, June, 1914.

facts, however, it is often astonishing how well an organ has functionated during life in spite of the finding at necropsy of pretty definite and fairly diffuse lesions.

In fact, in some cases, the question arises whether the lesions which we find associated with disturbance of function are really the cause of the disturbance or merely concomitant. The mere fact that the development of clearly manifest lesions usually consumes considerable time (usually twenty-four hours and often much more) is very suggestive in this regard. If the lesions are to be the cause of the disturbance in function which we observe, they must precede the disturbance, but should not follow it. If, for instance, we produce a disturbance of the renal function by means of some renal irritant which manifests itself by albuminuria we observe the disturbances of function, if the irritation is sufficiently strong, within less than one hour, at which time even the most careful histologic study fails to reveal any change, whereas well-marked anatomic lesions develop as a rule in the course of the next twenty-four or thirty-six hours. Such lesions cannot very well be the cause of the disturbance in function; still they do indicate that by the insult the cells were injured in such a way as to lead eventually to a change in their structure. In other words, what we see is not the cause of the disturbance in function but the final result of a cell injury the actual nature of which is not demonstrable by the means at present at our disposal. This appears to me to be the reason why so many of the degenerative lesions resemble autolytic changes which take place in the dead tissue. Still, they are valuable, because after a while at least they do show us that the cells have been injured. I believe, however, that it is worth while to emphasize this fact that sometimes the lesions are secondary to a primary insult not associated with demonstrable anatomic changes because in the hurry of our teaching or in the abbreviated parlance of even scientific reports it is often lost sight of.

It has been said by some that further efforts in the refinement of our technic in this direction are apparently hopeless and a mere waste of time, and there may be some grain of truth in this statement. Still, I believe it is hazardous to prejudge a case of this kind and it would seem to be better policy to encourage men who have a natural bent along these lines, because, after all, the better the fundamental facts relating to the structural minutiae of the cells are worked out, the more secure the structure of our scientific edifice will be.

On the other hand, I know, from personal experience that there are large and important fields in pathologic anatomy which need much new work before they are anywhere near their possible completion. From this point of view, in many cases, the surface seems hardly to have been scratched. The common types have been fairly well established, but the more intricate problems, especially again in relation to the functional disturbances, have been hardly worked up at all. When we descend from the textbook picture to the individual case and to a careful scrutiny of its individual problems, we find no end of stimulation to investigation and research, even along anatomic lines.

In our study of function we cannot of course rest entirely on an anatomic basis, because evidently many problems connected with this subject are not open to anatomic investigation. The structural changes which

underlie them are so minute that they cannot be approached by means of the scalpel or the microscope. Recently, for instance, studies have been carried in our laboratory in regard to the severe disturbance in nitrogen metabolism which follow anaphylactic shock. They do not seem to be associated with any discernible lesions in any of the important organs, in spite of the fact that they persist for a considerable period of time and eventually cause the death of the animals. This is by no means an isolated example even if we exclude from consideration the central nervous system, the mysteries of which, in spite of great advances in our knowledge, are still so baffling.

In many of these problems undoubtedly chemistry or physical chemistry will step in and furnish us new clues. Judging from the material which has already accumulated along these lines the prospect for further important developments seems to be unusually bright. Still there are intrinsic difficulties in method which it will be difficult to overcome. As Meltzer has pointed out, chemical research labors under the same disadvantage as pathologic anatomy in dealing largely with dead material. There is also the distinct disadvantage of being confined so far to rather gross procedures which do not permit of a utilization of our knowledge of the finer histologic detail of the organs studied.

Microchemistry, that is, the application of chemical methods to histologic sections, has bridged over this gap in some instances and may do so in more, but, unfortunately, characteristic chemical reactions are to be obtained from bodies only when they are more or less dissociated, and the more intimately they are bound up with the living protoplasm, the less easily they are detected by chemical means without resorting to violent interference.

On account of these difficulties in the way of a direct application of exact chemical and physico-chemical methods, a large body of hypotheses has developed which is based on our present knowledge in organic chemistry, but which, so far, is beyond the reach of actual demonstration. I need only to allude to our chemical conceptions with regard to enzymes, toxins and the various immunity reactions in order to bring out this point clearly. It is to be hoped that a refinement of our present methods will permit us eventually to develop this knowledge to a satisfactory conclusion, and if we do succeed, our ideas with regard to the relation of chemical structure to function will necessarily be advanced immeasurably.

Progress along any of the lines mentioned—pathologic anatomy, parasitology, biologic chemistry and biologic physics—is absolutely impossible without experimental work. In fact, the animal experiment is the touchstone to any new idea which may develop in the field of biology, including medicine. The final proof of any contention in the biologic sciences rests in the animal experiment. On the other hand, the experiment needs the control of the other methods in order to make quite certain that the experimental results are applicable to the case in question.

The experimental study of function itself is naturally of the greatest importance, quite immaterial whether we understand the underlying factors or not. For practical purposes the value of such experimental researches may be so great that it may well be questioned whether some of the energy now directed to the elucidation of more obscure general problems could not with advantage be diverted along these new

and fruitful channels. If we know the modifications in function arising from physical or chemical changes in the environment of the functioning cell, we at once obtain means of controlling such function more or less, and what this means to the physician who has to deal with manifestations of disturbed function in his patients needs no amplification. In this way he frequently may obtain the desired effect in spite of the fact that the ultimate mechanism of the action is unknown, and a complete knowledge of the same possibly unattainable.

Such studies of function under carefully selected and well-controlled experimental conditions may also permit of very interesting conclusions with regard to the mechanism involved. Our knowledge of the chemical control of glandular function has been obtained in this way. There is also no question that some serious errors arising from a merely anatomic study of the parts involved have been corrected by this method, but after all it is a method with its own advantages and its own palpable limitations like all others.

In conclusion, then, I wish to emphasize that our goal of a thorough understanding of the biologic processes in health and disease cannot be reached by one method alone. Men with varying inclinations and varying training have to cooperate in order to make progress, and the more intricate our problems grow the more the necessity of such cooperation becomes evident.

It is of course an impossibility for any man to be a master in all branches of biologic research, but a fair degree of familiarity with all is necessary, to produce, if I may borrow a German expression, a friendly understanding, to avoid misconceptions and the development of that narrowness of view to which I imagine Professor Henderson wished to refer. I believe that laboratories in pathology, just like those in physiology, pharmacology, hygiene and clinical medicine, should be ready at any time to take up a problem from whichever point of view appears to be the most hopeful, with whatever methods seem to be indicated, and, if necessary, from as many points of view and with as many variations in method as seem desirable.

THE PRESENT STATUS OF PYELOGRAPHY *

FLOYD E. KEENE, M.D.
AND
HENRY K. PANCOAST, M.D.
PHILADELPHIA

Sufficient evidence is furnished by the excellent work of Braasch and many others to establish without question of doubt the value of pyelography in the diagnosis of surgical diseases of the kidney and ureter. Additional testimony based on our own experience would mean merely a repetition of what has already been stated. Another phase of the subject, which is of equal importance and forms the theme of this paper, is the consideration of the harmful results that may follow collargol injection, its indications and limitations.

When we first began the use of pyelography, we shared the opinion of others that the injection of

collargol into the renal pelvis was free from danger and employed it routinely in all cases presenting symptoms which might be due to renal pathologic conditions. In the course of time we became convinced of the error of such a procedure. With increasing knowledge acquired from our own experience as well as that of others, we have put a decided limitation on the cases suitable for injection and have formulated a technic which we believe will reduce the disastrous sequelae of pyelography to the minimum.

That collargol produces little or no irritation of the pelvic mucosa seems to be proved by clinical and experimental evidence. Following injection in twenty of our cases, the urine rapidly lost the collargol stain, and microscopic examination was normal or showed only a slight excess of leukocytes with an occasional erythrocyte. Kidd¹ reports similar results. In his discussion of Kidd's paper, Walker states that he "has operated on a number of cases within a few days of the collargol examination and in every case the lining membrane of the renal pelvis was healthy and glistening even when the pelvic contents were deeply stained

Fig. 1.—Early tuberculosis of the kidney. From photomicrograph. Intense infiltration of collargol throughout all portions of the section, with well-marked destruction of kidney structure. High pressure used in making the injection.

with collargol. In some cases where nephrectomy was performed the mucous membrane was normal microscopically." This coincides with our own findings; in both specimens illustrated in this paper, the lining epithelium of the pelvis is normal although the kidney shows wide-spread changes. Blum,² on the other hand, reports extensive necrosis, but, as Strassmann³ points out, his experiments are open to criticism in that he used post-mortem specimens, and the changes which he ascribes to collargol could well have been cadaveric. The burden of proof, therefore, is that, so far as the renal pelvis is concerned, collargol is harmless.

That the injection may have a decidedly injurious effect on the kidney has been shown repeatedly and almost without exception; the pathologic reports detail the same results, namely, the tubules filled with collargol, which may extend into Bowman's capsules, rup-

ture of the tubules, peritubular round-cell infiltration, renal infarcts or areas of cortical necrosis. Strassmann alone maintains that the tubules are free, the collargol being taken up by the renal lymphatics or tissue clefts. The experimental work of Tennant,⁴ Oehlecker,⁵ Kidd and others, conclusively proves that collargol gains entrance to the kidney by way of the tubules and that the extent of involvement is directly dependent on the degree of pressure exerted in making

Fig. 2.—Same specimen as shown in Fig. 1. From photomicrograph. Argyrol in Bowman's capsule, also permeating the kidney tissue with a moderate degree of necrosis and round-cell infiltration.

the injection as well as the time that the solution is allowed to remain in the pelvis. The same results are reported clinically by Mason,⁶ Tennant⁴ and Troell.⁷ The accompanying photomicrographs (Figs. 1, 2 and 3) depict similar conditions. These injections were made during our earliest experience in pyelography and represent the ill results that may attend imperfect technic in types of disease in which, if used at all, the injection must be made with the greatest skill and care. Severe pain followed both injections and confirms Tennant in his statement that pain following collargol injection may have a graver significance than the mere overdistention of the pelvis, indicating the passage of the solution into the renal parenchyma.

The question naturally arises, Is the kidney permanently or seriously injured by collargol in the absence of superadded infection or such extensive lesions as infarction or necrosis? Pathologic evidence and clinical experience seem to indicate that this can be answered in the negative. Leukocytes, a few red blood-cells and hyaline casts may be present immediately following injection, but these soon disappear. Even in those cases in which violent pain and high fever have followed, such as reported by Vest⁸ and Zachrisson,⁹ the urine sooner or later returns to normal.

Evidence is available, therefore, which shows that wide-spread lesions of the kidney may result from collargol injection and as a rule go hand in hand with overdistention of the renal pelvis. In many cases, collargol may find its way into the straight tubules, but the resulting irritation of the renal parenchyma is usually trifling and produces no permanent injury. That a substance may be found which will be non-irritating as well as impermeable to the Roentgen ray is to be hoped for. Kelly and Lewis¹⁰ advocate silver iodid but their report is too meager to warrant acceptance until further accurate experimental and clinical evidence is submitted.

Our experience, together with a study of the cases reported in literature, convinces us that too much stress has been put on the supposed corrosive action of collargol, while in reality the fault lies in the method of injection or its application in types of disease which favor rapid permeation of the renal tissue.

As the result of his experiments with Berlin blue and other inert anilin dyes, Marcus¹¹ demonstrates with what ease trauma to the pelvis and kidney may be produced by even low pressure. If no injury were present, the coloring-matter merely lay in the pelvic clefts or ascended occasionally into the collecting tubules at the papillae, but was never found in the intratubular tissue. When the dye was found in the veins of the kidney, he invariably demonstrated a traumatic site of entrance in the pelvis or renal parenchyma. Under high pressure, it was an easy matter to produce a migration of any inert substance from the pelvis to the renal vein by way of the kidney, with emboli in various organs. He also shows, experimentally, that the site of rupture determines the area per-

meated by the dye which may be found in the renal vein, the subcapsular space or the peripelvic tissue.

The experimental work of Lewin¹² was done along similar lines and with like results, although he does not emphasize the importance of trauma as the exciting

factor in permitting the escape of the injected fluid. Emboli were found in the right heart, lungs and liver, corresponding to the recent report of Eisendrath¹³ and differing only in the fact that he used an anilin dye instead of collargol. The experiments of Strassmann, Kidd and Tennant, previously referred to, substantiate the findings of these investigators and show the possi-

(Troell) and one case of suppurative pyelonephritis (Schwartzwald¹⁵).

To these we add the cases herein reported, one of early tuberculosis and the other chronic pyelonephritis and hydronephrosis (Fig. 4). This is sufficient evidence to indicate that such lesions may act as at least contributing factors in the dissemination of collargol throughout the kidney, since they furnish ideal conditions for the production of a portal of entrance.

The effect of direct trauma by the ureteral catheter is nicely shown in the specimen of Mallory reported by Mason: "The collargol was injected into the kidney tissue as a result of running the catheter too far into the pelvis of the kidney. Evidently the point of the catheter went into a calyx and the fluid was injected under pressure into that calyx." Any one experienced in ureteral catheterization knows that unless the greatest care is used, it is an easy matter to traumatize the pelvis sufficiently to produce bleeding and thus bring about a condition similar to that seen in the specimen just mentioned.

Reviewing the cases reported in literature from the clinical point of view, pain following injection is the most frequent symptom. This may be very severe, requiring morphin for its relief, and persists for several hours or even days. Pain may follow the most careful manipulation in passing the catheter or the injection of only a few drops of collargol. In our experience this has occurred only rarely; when severe pain has resulted, it has been due to our faulty technic of catheterization or injection. When pyelography was first undertaken, we were inclined to ascribe this

Fig. 4.—Calculus pyonephrosis showing diffuse permeation of collargol throughout kidney. Type of case unsuitable for pyelography.

bilities of danger which attends injection under high pressure, and also the relative freedom from danger when little or no distention of the pelvis is produced.

It is doubtless true that, in the earlier days of pyelography, many instances of severe pain or disastrous results following injection were due to an erroneous conception concerning the capacity of a normal pelvis. At that time the limits were stated by various observers as varying from 15 to 30 c.c., while at present we know that the capacity is between 2 and 5 c.c. It is only natural to assume, therefore, that, in making the injection, the normal capacity was many times exceeded.

We are firmly convinced that solution of continuity of tissue, whether by ulceration, or direct or indirect trauma, plays an important rôle in permitting the escape of collargol from the pelvis. The work of Marcus already referred to shows how even low grades of distention can break the pelvic lining in normal kidneys. In kidneys altered by disease, whether this be a thinning out as in hydronephrosis, an ulceration as in tuberculosis or tumor, or increased friability due to pyogenic infection, it is self-evident that ruptures of varying degrees are more prone to result. Of the reports in literature of cases in which extensive changes have been produced by collargol, it is interesting to note three cases of hypernephroma (Mason, Oehlecker and Rössle¹⁴), one case of pyonephrosis

Fig. 5.—Colon bacillus pyelitis with marked dilatation of pelvis due to ureteral kink. Symptoms relieved by pelvic lavage. The usual methods of treatment together with autogenous vaccines had been unsuccessful.

pain to the irritation of the collargol, and varied the percentage of the solution from 1 to 10, with no apparent relationship between the strength of the solution and the intensity or absence of pain. It was evident that some other factor was active. We found

that the frequency of pain was greatly diminished by inserting the catheter only part way up the ureter instead of into the pelvis. This plan is open to criticism in that it gives no idea of the pelvic capacity, but it does indicate that the avoidance of trauma to the pelvic mucosa is an important factor in lessening the harmful results, of which pain is often the only

pain whatever, proving conclusively its great advantage over the older method.

Several cases are reported in which fever has followed injection, persisting for days and in a few instances attended by the development of perirenal suppuration. As first pointed out by Voelcher and observed by Braasch and many others, collargol is not uncommonly found in the peripelvic tissue and produces little or no inflammatory reaction. We are convinced that a rise in temperature is due not to collargol *per se*, but that faulty technic has permitted the introduction of infection, with collargol as the medium by which it is carried to the kidney or its surrounding tissues.

Lastly, three deaths are reported as occurring after collargol injection. The often-quoted case of Rössle has been criticized by Strassmann who advances arguments which tend to disprove that collargol was the cause of death. More recently a second case is reported by Rosenblatt and Morgandies,¹⁷ in which a state of shock developed at the time of injection with death several hours later. In this case of suspected hydronephrosis, 40 c.c. of a 5 per cent. collargol solution was injected without difficulty. A post-mortem examination was not performed nor was the kidney examined microscopically. The perirenal tissues were widely infiltrated with collargol, there was no collargol in the pelvis or ureter and only a "minimal" tear was visible in the kidney tissue. In a case reported by Vest, death resulted on the fourteenth day after operation. Acidosis and acute dilatation of the stomach were postoperative complications. Vest does not

Fig. 6.—Stricture of ureter. Marked dilatation of ureter above stricture, and pyelonephritis of gonococcal origin. Pyelography was employed in order to eliminate calculus as a possible cause of ureteral obstruction. Lavage and collargol instillation resulted in temporary improvement.

symptom. As further proof of the ill effects of trauma, we have observed that pain almost constantly accompanies injection in cases in which bleeding follows catheterization.

The second and by far the most important cause of pain is overdistention of the renal pelvis: Whether we accept the evidence of Marcus that overdistention produces solution of continuity of the pelvic lining, or of other observers that the collargol ascends directly into the straight tubules without previous pelvic injury, the fact remains that, as a rule, the degree of permeation in the kidney is in direct relationship to the amount of pressure exerted by the distending medium.

We are in full accord with Tennant's statement that pain indicates in many instances the passage of collargol into the kidney tubules, and is not merely a colic incident to an overfilled pelvis. If the latter were true, the pain should cease shortly after the relief of pressure rather than persist for hours or days. We ascribe it to increased tension of the renal capsule, produced primarily by the sudden increase in volume of the kidney due to the entrance of collargol, and secondarily to reactive changes within the kidney incident to the injection of a mildly irritating, foreign substance. In seventy cases in which the piston syringe was employed, pain resulted in over 10 per cent.; in our last thirty cases, we have used the gravity method of injection as recommended by Thomas¹⁶ with no

Fig. 7.—The roentgenogram failed to demonstrate a calculus. The catheter met an obstruction 13 cm. from the ureteral orifice. By means of a collargol injection, the calculus was clearly defined, together with a hydro-ureter and hydronephrosis.

assert that death was due to collargol poisoning, but draws attention to the interesting fact that, as in Rössle's case, hemorrhagic diathesis developed a few days before death. In his preliminary report, Eisen-

16. Thomas, G. J.: An Apparatus for the Injection and Lavage of the Pelvis and the Ureters, THE JOURNAL A. M. A., Jan. 18, 1913, p. 184.

17. Rosenblatt and Morgandies: Verhandl. d. deutsch. Röntg. Gesellsch., 1913, ix, 81.

Each has shown experimentally that death may result from emboli in various organs, but this has occurred only when collargol was injected under very high pressure. That similar results may follow injection in man is of course true, but with ordinary care and skill, we can state without fear of contradiction that this danger can be entirely eliminated.

Fig. 8.—History in this case indicated ureteral calculus. A small cystic mass lay to the side of the uterus and the roentgenogram showed a shadow along the course of the ureter. Pycnography demonstrated a normal pelvis and ureter and an extra-ureteral shadow, which operation proved to be a tooth in a dermoid cyst.

CYSTOSCOPIC TECHNIC

Basing our ideas on experimental evidence as well as clinical experience, we have formulated certain points in technic which, in our opinion, are of importance in avoiding the untoward results of collargol injection. The greatest care as regards asepsis cannot be too strongly emphasized. The ureteral catheter should not exceed No. 6 in size, it must be free from rough surfaces and pliable so as easily to follow any change in the course of the ureter; to avoid trauma, we never use a stiletted catheter. The catheter is inserted for a distance of 20 cm. and its further progress is made extremely slowly until the slightest buckling occurs, which indicates that its tip has reached the pelvis. It is then withdrawn 1 or 2 cm. and the character of the urinary outflow is observed to determine, if possible, the presence or absence of pelvic dilatation. The catheter is then withdrawn 10 cm. and the injection made. By so doing the danger of wounding the pelvis is minimized and the tip of the catheter is below the level at which the majority of ureteral kinks are found.

If the urine is blood-stained, the injection is not made, a subsequent examination being advised at an interval of at least seven days. When an obstruction is encountered along the ureter, we do not attempt forcibly to overcome it, but pass a smaller catheter; if its passage is likewise impeded, the collargol is injected and in the majority of instances, will find its

way upward. The forcible passage of the ureteral catheter is to be condemned under any circumstance, but this is especially true when injection is to follow. We are opposed to the routine practice of simultaneous injection of both kidneys; when bilateral disease is suspected, the injections are made at two sittings. If for any reason, the roentgenogram is unsatisfactory, we make it a rule to allow several days to elapse before attempting a second injection.

The collargol is freshly prepared for each case; the crystals are thrown into a small mortar containing boiling water and when cooled are thoroughly dissolved by stirring with a pestle. The solution is filtered through cotton and gauze and is ready for injection. The strength of the solution varies from 5 to 10 per cent., depending on the thickness of the abdominal walls. In making the injection, we use a 30 c.c. buret connected with a short tube and stop-cock. To start the flow through the catheter, elevation of the buret to about 3 feet will be necessary but it is immediately lowered and allowed to flow in at an elevation of not more than 1 foot with a No. 6, and 2 feet with a No. 5 catheter. The injection is discontinued when the column of collargol ceases to fall or the patient experiences the first slight sensation of fullness in the kidney region. After the picture is taken, the collargol is drained off and the catheter removed.

We make it an invariable rule to keep our patients under observation in the hospital for twenty-four hours after injection and prescribe copious draughts of water during the first six hours. When retention from

Fig. 9.—Ptosis of the left kidney with hydronephrosis. The catheter met an obstruction 4 cm. from the ureteral orifice. Pycnography demonstrated that the obstruction was not pathologic, but due to an abrupt change in the course of the normal ureter.

angulation of the ureter due to ptosis is suspected, the patient is required to remain in bed for twelve hours after the injection. This facilitates free drainage of any collargol that may remain in the pelvis of the kidney.

ROENTGENOGRAPHIC TECHNIC

The diagnosis of renal and ureteral conditions by pyelography depends on the correct interpretation of the roentgenogram made immediately after a careful ureteral catheterization and injection with the opaque solution. While each step is of equal importance, and each without the other is of little or no value, roentgenography plays but a minor part in the procedure as a whole. It is to be regarded simply as a means of accurately demonstrating and recording what the cystoscopist has done. The real value of the method arises in a very large measure from the technic of the cystoscopist in creating correct appearances for the roentgenogram to portray in order to demonstrate existing conditions accurately.

When employed as a safe and necessary procedure, pyelography has a very limited range of application as compared to the usual routine roentgenoscopy of the urinary tract. It is to be employed, as a rule, there-

Fig. 10.—Beginning dilatation of the pelvis in a case of nephroptosis.

fore, only after the usual methods have failed to show any condition satisfactorily explaining the clinical phenomena present. Certainly, whenever calculus is suspected, the usual routine roentgenoscopy should always be resorted to first, as the injection of collargol may not only be unnecessary but is likely to interfere with the detection of a stone, especially in the kidney. Instances are recorded, on the other hand, in which the colloidal silver injection has rendered a calculus sufficiently opaque to cast a perceptible shadow when it was not detected by the simple roentgenoscopy alone. We are able to cite one experience of this kind in connection with a ureteral stone which was distinctly shown by the collargol injection, whereas no shadow could be detected in roentgenograms made at previous and subsequent examinations in the usual manner. Of course, such instances are exceptional.

There is little to be said of the roentgenographic technic *per se*. Preliminary preparation of the patient is always essential, and comprises the withholding of

food, pills and tablets, and the thorough evacuation of the intestinal tract. As we have found castor-oil disagreeable and not always satisfactory in removal of gas, we have recently adopted the use of compound cathartic pills pulverized and administered in capsules, and have found this procedure more efficacious.

Compression, which is so essential in the usual roentgenoscopy of the urinary tract, had best be avoided in connection with pyelography, for obvious reasons. When stout individuals are to be examined, the intensifying screen may become essential, if not used routinely.

In the early days of pyelography, Stover advocated the use of a table whereby one exposure could be made in the usual horizontal posture, and repeated immediately in the semirecumbent or vertical position by tilting the table. Such a procedure is obviously useful in the diagnosis of ureteral kinks associated with movable kidneys, but we have found it by no means essential. The substitute performance of having the patient get off the table and stand for the second exposure is to be condemned.

In our analysis of the cases reported in literature, it is evident that the harmful effects of collargol have, in many instances, been due to sins of omission or commission on the part of the operator and should not be held to the discredit of the injection itself. On the other hand, it has been shown that, even with the greatest skill and care, there are possibilities of danger which should serve as a warning against the indiscriminate injection of collargol, irrespective of the underlying pathology. For this reason, we resort to pyelography only when an accurate diagnosis cannot be made by other methods of examination.

We are opposed to its use in depicting interesting anomalies when such a procedure means merely a graphic representation of what may be accomplished by the method. We are likewise opposed to its indiscriminate use in all types of renal pathology; for experimental as well as clinical evidence indicates that possibilities of harm are certainly increased in the presence of ulceration, infection or retention of the solution in the pelvis. For this reason, with only rare exceptions is the injection made in suspected cases of neoplasm, tuberculosis or large hydronephrosis. Likewise, in those infections other than tuberculosis, we hesitate to employ collargol until other methods of diagnosis have been exhausted. It is of the utmost importance in the treatment of pyelitis to determine whether we are dealing with a mechanical dilatation of the pelvis with superimposed infection or with a true primary infectious pyelitis, and if other methods fail to reveal the desired information, the risk of pyelography is far outweighed by the accurate data which it affords.

When renal or ureteral calculi can be definitely recognized in the roentgenogram, little or no additional information will be afforded by pyelography; the injection is indicated only when the position and character of the shadow make it impossible to determine whether it lies within the kidney or ureter or in adjacent structures. This applies especially to those cases in which in addition to the shadow along the course of the lower ureter, the catheter meets with an obstruction at a corresponding level. Such evidence is of course strongly in favor of calculus, but is by no means positive, since inability to pass the catheter above a certain level is not infrequently due to an

abrupt change in the course of the normal ureter. This point will be quickly determined by the presence or absence of ureteral dilatation above the site of obstruction.

The pyelograph serves its greatest field of usefulness in detecting the earlier stages of hydronephrosis due to mechanical blockage of the ureter other than that caused by stone. In fact, it is the only means at our command which permits the diagnosis to be made without question of doubt. This applies likewise to certain congenital anomalies, especially the horseshoe and the dystopic kidney. Under these circumstances, if proper technic be employed, collargol injection can be made with but the barest possibility of harmful sequelae.

That exceptions to these general rules in the selection of cases will arise from time to time, is quite obvious, but such exceptions are rare, and in no way detract from the general principles which we have formulated for our own guidance. We may err on the side of conservatism, but we are satisfied that it is likewise on the side of safety, for we are convinced that possibilities of danger exist even under the most ideal circumstances. In the majority of instances, however, disastrous results following collargol injection have been due not to the use but to the abuse of the method, and we are confident that if greater care be given to the technic of injection as well as to the selection of cases, the dangers of pyelography will be of minor importance as compared to the valuable information which its use will afford.

116 South Nineteenth Street.

ABSTRACT OF DISCUSSION

DR. W. F. BRAASCH, Rochester, Minn.: Undoubtedly Drs. Keene and Pancoast should be given great credit for calling our attention to the possibility of ill results from the use of pyelography. If we remember the history of cystoscopy we shall recall that illness and death were reported, so that for a while the method fell into discredit. Ureteral catheterization also was criticised so severely that many would not permit patients to be so treated. While undoubtedly its abuse may cause harmful results, nevertheless it will remain as an invaluable method of diagnosis in conditions in the ureteral tract. It is a peculiar thing that of the deaths recently reported as the result of pyelography, the cases have been almost entirely in the hands of men of little experience. Our experience in 2,000 cases treated with pyelography has not given us serious results which could be ascribed to its use in any case. In my early use of the method I have observed three cases of cortical lesion in which I should not have used it. I have laid down the fundamental rule never to make more exploration of the tract than is necessary for diagnosis. There is a long list of conditions in which I have diagnosed obscure symptomatology which could not have been diagnosed in any other way. Our endeavor should be to find some substance which is harmless and which can be injected without causing the colloidal poisoning. If drainage is interfered with there will be trouble; if the kidney is overdistended there will be trouble. By means of the gravity method we have overcome the dangers of overdistention, but we cannot always overcome the dangers of overretention, but the dangers are reduced to a minimum. The silver iodid advised by Kelly seems to me to be a valuable adjunct. It cannot be employed in the gravity method, but must be employed with the syringe because of its viscosity. The ideal substance should be sufficiently liquid to be used in the gravity method and one which would not cause necrosis if retained. Pyelography should be in the hands only of men with wide experience in the work.

DR. HENRY DAWSON FURNISS, New York: There are still many dangers in pyelography, due to the mechanical insult of its performance and to the irritating effect and toxicity of the substances used. The ideal substance must be non-irritating, non-toxic and soluble in both water and the blood. Eisendrath has done some good experimental work in the injection of argyrol and collargol under pressure, and has found these substances not only in the tubules of the kidney, but also in the interstitial connective tissue, as well as in other organs of the body. The wide distribution he found due to entrance of the collargol through ruptured veins. In the Genito-Urinary Section were reported four or five fatalities following the use of collargol. In some, death was within a short time and in others followed within ten days or two weeks. In these late fatalities a hemorrhagic condition developed, with bleeding from the mouth, nose, stomach and under the skin; there were superficial ulcers in the mouth. In making pyelographs, my technic is to fill the bladder with boracic acid solution, put the patient on the table, have the Roentgen-ray plate and tube adjusted, then catheterize the ureter using a soft No. 5 or 6 catheter, clamp the cystoscope in position with a holder, and then make the injection under gravity. This saves a lot of unnecessary moving of the patient, which is disagreeable and tends to displace the catheter. The soft catheter is used, as stiff ones are capable of injuring the kidney substance so that the collargol can enter the circulation of the kidney substance. By using small catheters there is less danger of harm, as the collargol can escape alongside of the catheter. Even with the most careful technic severe pain often attends making a pyelograph. I am of the opinion that the pain is due to other factors than the simple distention, as I have never noticed such long and severe pain in the cases where I have distended the renal pelvis for diagnosis according to the method of Kelly. I agree with Drs. Keene and Pancoast that pyelography is a most valuable diagnostic aid and one to be used only when other methods do not furnish us the necessary knowledge. It is especially useful in early hydronephrosis and easily passable strictures of the ureter.

DR. D. N. EISENDRATH, Chicago: I have had occasion to use pyelography a great deal but have felt that I was not justified in using it with the syringe, unless I knew just where the danger-line was. In my first case the patient, who was 54 years old, died within half an hour after the injection. I made up my mind there must be some reason why the collargol in the urine caused trouble. We knew that the gravity method was apparently the safest and so we elevated a column of collargol $3\frac{1}{2}$ feet above the level of the table and caused a pressure of 30 mm., injecting a certain series of animals with 10 per cent. collargol, about 8 ounces, and killed them at different intervals. We were the first to use the manometer and by measurement were able to state the exact amount of pressure used to inject the collargol into the high renal pelvis. In this first series there were no changes; we could find no collargol except in one kidney. We had proved, experimentally, that the collargol was perfectly safe so long as we did not raise the pressure above 30 mm. In the second series we increased our pressure from 30 to 70 mm. and still kept as close as we could to the capacity of the renal pelvis of the dog—from 2 to $7\frac{1}{2}$ c.c.—seldom over 5 c.c. The animal lived. There was collargol in the lungs, in small quantity in the liver and in the kidney. In the animals that lived for thirty days after the experiments, what Drs. Keene and Pancoast have said, was true; the collargol did not kill off the epithelium, but we got much inflammatory reaction. Then we decided to increase our pressure. The first animal in this series we subjected to a pressure of 100 mm. and injected 20 c.c. and it died in five minutes from the time of beginning the injection. By the time the last of the fluid was in, the animal was dead. At necropsy we found that the lungs were perfectly black. They evidently had been filled completely with the collargol. The collargol filled every capillary of the lung as if injected for histologic purposes. The liver showed nodules, with quantities of collargol in the form of

The exception taken to the exclusion method of Doyen¹ and von Eiselsberg,² tried out by Haberer,⁴ Jonnesco,⁵ Jianu,⁶ Girard,⁷ Leriche,⁷ Bressot,⁷ Grossman,⁷ and Küttner,⁸ is the difficulty of execution and the increased percentage of mortality.

Kolb,⁹ Bircher,¹⁰ Hercher,¹¹ Hoffmann,¹² and Göbell¹³ have tried out the Wilms¹⁴ method with the strip of living tissue, and Naselli,¹⁵ using various tissues in six experiments, found the closure only temporary.

Brewer¹⁶ excluded the pylorus in nine dog experiments with an aluminum strip, finding the lumen non-patent at necropsy not later than two months and ten days.

Berg,¹⁷ Pool,¹⁸ Momburg,¹⁹ Corner,²⁰ Renton,²¹ Ward²² and Parlavacchia²³ have used a non-elastic ligature to occlude the pylorus, and report good results; but the large majority of men who have experimented with this method find that the ligatures rapidly cut through into the lumen and are passed along with the intestinal contents.

Infolding or kinking methods as practiced by Blad,²⁴ Mertens,²⁵ Sequinot²⁶ and Mariani²⁷ give only a temporary occlusion of the pylorus.

up the pylorus, thus permitting the lesion to heal while allowing the pylorus to become permeable after all danger of irritation of the ulcer is past.

I have seen W. J. Mayo and Mr. Moynihan infold with a purse-string, ulcers of the duodenum. Both seemed of the opinion that in this way temporary obstruction was produced and the value of the gastro-enterostomy enhanced. No theoretical deduction can be lightly weighed in the balance against any statement based on the practical results of two surgeons whose experience has been so rich and whose powers of logical deduction have proved so valuable.

A study of the intricate physiologic arrangement, which exists for taking care of the acid stomach contents inclines one to preserve the same in the absence of weighty reasons to the contrary.

Apparently the stomach contents are sharply divided for a long time into two parts. Unacidified salivary digestion may go on two hours in the cardiac half according to Pawlow.²⁸

The anatomic ground for this was suggested by Klemensiewicz,²⁹ who was the first to attempt isolation of the pyloric and fundus pouches, to get two pure secretions. In 1875 he excluded (bilaterally) a

Fig. 4.—The step here described may be used instead of that shown in Figure 3. Here the first row of sutures described in Figure 2 is inverted in the ordinary manner, the V being left open.

Fig. 5.—A spatula is thrust behind the stomach from below upper and a skewer driven through both walls of the viscus and out again, in such a way that it holds up about half of it when measured transversely. The highly vascular portion of the stomach is not interfered with.

Fig. 6.—A slit clamp is applied behind the skewer and several mattress-sutures introduced through all the layers of the anterior and of the posterior walls.

Not a few workers in this field seem to be convinced that the best technic is that which temporarily closes

pylorus sack in the dog and withdrew an alkaline secretion. He kept no dog more than seventy-two hours. Heidenheim³⁰ kept one of six operated on thus for six months and got the same alkaline fluid with pepsin and rennin. He³¹ found that pyloric secretion had no effect on the wall about the fistula. Not satisfied with this knowledge, he³² isolated a fundus sack in eight dogs, kept one several weeks and withdrew a secretion containing pepsin and hydrochloric acid of higher concentration than the normal from a whole stomach (mixed with saliva and alkaline pyloric juice). It digested the tissues about his fistula.

Sick³³ withdrew through the tube, separately, the contents from fundus and pyloric portions. He found the two samples (in healthy stomachs) to be quite

different, physically and chemically. He got no or little hydrochloric acid from the pyloric portion, but obtained pepsin and rennin from it, though perhaps not so much as from the fundus.

In view of this knowledge, we must consider the pyloric antrum (as far as its secretion is concerned) as part of the intestine. Now many unfortunate experiences have proved that secondary jejunal ulcers are commoner, the lower, stomach contents are dumped into the bowel by gastro-enterostomy. In other words, the farther we go from the mucosa, in which acid secretion originates, the less automatic protection we find against its immediate effects.

We find far the greater part of all ulcers in the pyloric antrum and upper duodenum, regions which produce no acid, but which are regularly and frequently exposed to its action.

Cohnheim,³⁴ using from 6 to 8 cm. water, finds steady pressure on the contents of the fundus, while in the pyloric antrum, regular, powerful, peristaltic waves run along at regular intervals (six to the minute) according to Cannon³⁵ toward the pylorus and inject the food far into the duodenum.

Pawlow²⁸ agrees with Cannon³⁵ that it is the acid in

2. Closure of the pylorus itself cannot protect a gastric ulcer proximal to it, even in the presence of gastro-enterostomy, since the pyloric antrum drives stomach contents as far as possible toward the closed pylorus before letting it fall into the new opening. *Gastro-enterostomy alone* seems to have done less good the farther from the pylorus a stomach lesion has been found. However, my experience with unilateral exclusion of the affected area in such cases has been most satisfactory.

It takes the place of excision of gastric ulcer, or pylorotomy where the latter presents extreme technical difficulties.

A large ulcer perforating deeply into the structure of the pancreas, liver or other organs is most simply treated by exclusion.

It prevents the gastric contents passing over an ulcer; stops pain, prevents hemorrhage and puts the excluded portion at rest, allowing the ulcer to heal, thus decreasing the likelihood of secondary cancer.

3. Any form of exclusion of the pyloric antrum which prevents food passing over it accomplishes as much as does complete transverse division of the organ. Cohnheim teaches that the innervation of the

Fig. 7.—The skewer is cut out and the edges cauterized to avoid hemorrhage.

Fig. 9.—The cut surfaces are hidden by a row of Lembert sutures.

the duodenum which causes the pylorus to close and the gradual alkalinization of the duodenal contents to a given point which causes this sphincter to open again. One must, in view of such reasoning, hesitate *especially in the presence of high acidity* before permanently dumping stomach contents onto a mucous surface ill-prepared to receive the same.

CONCLUSIONS

1. Our real knowledge of ulcer is so meager at present that we are not prepared to deal with remedial conditions which do more than temporarily relieve the anatomic condition which is the expression rather than the origin of this disease. In the duodenum infolding (temporary obstruction) and gastro-enterostomy accomplish this without forever diverting stomach contents to a mucosa ill prepared to receive it. This is shown by a study of the enormous material of the Mayos and Moynihan.

stomach and pyloric musculatures is chiefly governed by automatic centers in the organ. This much is known although the exact action of the stomach's nerve mechanism is not understood. We cannot hope to stop secretion in the pyloric antrum by complete transverse division of the organ since Pawlow has shown that foods stimulate gastric secretion after the stomach is completely isolated from nerve connections, and hence through intrinsic ganglion by reflex nervous origin.

4. Both the methods I am proposing are simpler, take less time and encounter fewer blood-vessels than does transverse complete division of the organ. Experimentally they produced results similar to it, while clinically they seem to have been equally successful.

5. My first method (Figs. 1 to 4, inclusive) may seem the more convincing on theoretical grounds. The second (Figs. 5 to 9, inclusive) is the easier to perform and is less bloody, but it violates the time-honored principle that mucous surfaces are not to be approximated. The two methods seem to have given

equally good results in experimental work; the same seems to be the case in my clinical work, although this is not so easily ascertained. I leave the reader to choose between the two, after trying them.

400 Metropolitan Building.

ABSTRACT OF DISCUSSION

DR. WILLIAM L. RODMAN, Philadelphia: So many methods have been proposed from time to time to exclude the pylorus that we must agree that it is questionable if they do exclude. We know that the early methods which were introduced were absolute failures. Practically all methods except within recent years were looked on as failures, beneficial only for a time. So von Eiselsberg devised the radical procedure of cutting across the pylorus, sewing up the pyloric and the duodenal ends, thus making the two openings in the gastrointestinal tract to close. I am satisfied that the method described by Dr. Bartlett is excellent and, moreover, less mortality would follow his method than that of many others, and yet, he has had two deaths. The cases are too few, the time too short to say what the ultimate results will be, but I am inclined to agree with him that when the stomach is bound down by adhesions and a resection cannot be done, it would, perhaps, be well to use his second method. There would, I think, be less mortality than after the first. I have never performed pyloric exclusion, but if I do, shall use Dr. Bartlett's method, as it appears quicker, safer and seems to accomplish all that is accomplished by von Eiselsberg's operation. The question arises, Why operate, when, by removing a little more tissue than is removed in von Eiselsberg's operation, the ulcer-bearing area may be excluded. Dr. Bartlett's operation or any method of exclusion cannot prevent subsequent hemorrhage perforation or cancer of the stomach. There are, annually, 75,000 deaths in the United States from cancer, and more than 25,000 of them are from cancer of the stomach. Why shall we leave a lesion with so great potentialities in the stomach if it can be removed with practically the same mortality as these other methods, ingenious in a way, but which do not go to the root of the trouble? It has simply been from an exaggerated fear of the mortality. Is that justified? Recently, before the American Surgical Association, I reported a large number (375) of pylorotomies and partial gastrectomies done by American surgeons with a mortality of 4 per cent. I do not think one can do the von Eiselsberg operation with a smaller mortality and yet, in that operation, you are leaving the lesion behind. The fact stated by that great pathologist, Virchow, must be constantly kept before the mind, that 35 per cent. of all cancers in the human body are in the stomach. The time to operate on cancer of the stomach is when it is an ulcer. It has been conclusively shown that a vast preponderance of gastric carcinomas are preceded by ulcers. All precancerous lesions should be attacked radically, for in this way only shall we be doing our full duty.

DR. W. D. HAGGARD, Nashville: I have not applied Dr. Bartlett's procedure to the human subject but expect to use it in suitable cases. There have been many attempts to exclude the pylorus; the old ligature has been unsatisfactory. Dr. Bartlett's operation is simple and seems worthy of trial in some cases. I would not differ with Dr. Rodman in doing partial gastrectomy in suitable cases, but the surgeons of this country ought to reserve that for the extreme case. Now it cannot be denied that an operation of that magnitude in average hands is not going to be attended by the minimum mortality of 4 per cent. that has been gathered from the great clinics of the country. This Association is to establish certain lines of procedure for the average American surgeon. While it is true that of those cases of ulcer which develop cancer, 70-odd per cent. have developed on ulcer, it does not mean that all cases of ulcer will develop into cancer. Witness the very few cases that have ever been reported of a secondary malignant degeneration of an ulcer that has been operated on by gastro-enterostomy or any of the other well-recognized measures. Now, if, at the

time of operation, you are clinically or pathologically undecided as to whether or not the case is malignant, then Rodman's operation is the operation of election. It seems to me, however, that in the average case the principles laid down by Dr. Bartlett are the ones we should apply. Any measure that has just been introduced is, of course, going to have a hard voyage, but I do believe that if we practice this operation we shall find it applicable to a large number of patients who will do better than if we perform gastro-enterostomy.

DR. W. C. JONES, Chicago: What evidence does Dr. Bartlett have that his method produces complete pyloric obstruction? This point seems doubtful to me. I have been doing some experimental work with Dr. Carl Beck of Chicago, in making an artificial tube from the greater curvature of the stomach, using this tube for gastro-enterostomy instead of connecting the intestine with the unaltered stomach. In this work, the pyloric end of the stomach was narrowed as much or more than occurs in Dr. Bartlett's operation; yet we found by means of the Roentgen ray that the stomach contents passed largely through the pylorus. Passing a ligature around the pylorus did no good, as might have been expected. The most satisfactory and the simplest method we found of making the obstruction sure was complete incision of the pylorus and infolding of the cut ends. This procedure is very simple, is absolutely certain, and on the whole, leaves little to be desired.

DR. WILLARD BARTLETT, St. Louis: I was probably not understood when I stated that I had the stomachs from two necropsies and the stomachs of 17 or 18 dogs in evidence of the fact that the obstruction produced seems to be as complete as the operation of complete transversion with folding in of the ends. I cannot explain the difference, however, between this and Dr. Jones' method, but I shall be glad to study it.

A MICROCEPHALIC IDIOT WITH MALFORMATION OF BRAIN*

REPORT OF A CASE

ARTHUR K. PETERY, M.D.
NORRISTOWN, PA.

The case which I report is that of a patient who has aroused considerable curiosity among those who have seen him. The parents of the patient were interviewed by myself and furnished what information they could, freely and willingly. They appeared to be working people of the average intelligence, the father being 59 years of age, healthy, a blacksmith, a steady worker and a moderate user of alcoholics, though he has never been intoxicated. His mother is still living, aged 83, while his father died at the age of 62 from rheumatism. The patient's mother is living at the age of 55 and at present is passing through the menopause; she was the mother of eight children, who, with the exception of the patient, are all living and normal. She is strictly temperate in habits; her father was killed at the age of 38 in a railroad accident and her mother died at the age of 70, the result of heat exhaustion.

There is no history of any miscarriages, tuberculosis, malignancy or mental diseases in the family, and the only explanation that the mother can offer for the condition of the patient is that when she was four or five months pregnant they moved from one house to another, and she did a lot of hard work and heavy lifting, but was not injured and nothing unusual occurred.

REPORT OF CASE

Personal History.—The patient, the third child in a family of eight, was born April 17, 1884, at full term. "Birth was

* Read before the Philadelphia Psychiatric Society, March 13, 1914.

easy"; the child weighed about 6 pounds. The family noticed that the head was quite small and had "no openings on top," but thought nothing of it. The child was breast-fed to the age of 2 years when he was weaned, but it has always been necessary to feed him with a spoon. He never made any effort to learn to talk and first began to walk at the age of 3 years. He never walked a great deal, but when he did try, it was on his toes, never placing his foot flat on the ground. His condition first attracted the special attention of his parents at about the age of 5 years when they were told that the child would never talk or be of any account in the world. As soon as he was able to sit alone he would place his feet under him and when in bed would lie with the lower extremi-

Fig. 1.—Facial expression of patient in animation.

ties contracted. He constantly pounded with his hands on anything near him and the parents explain his large hands by this action. As he grew older he learned to know the various members of the family by sight; was usually good-natured, but at times showed a temper. When strangers came into the house he would notice the difference; would laugh and become noisy and excited.

It was always necessary to tie him to his chair, otherwise he would get into mischief by pulling things over and destroying them, and if the other children came within reach he would pull their hair with both hands, though he seemed to enjoy watching them playing about him. He was inclined to be destructive at every opportunity and if he found a small hole in his clothing would work at it until the garment was destroyed. He was never able to talk or to care for his personal wants.

Owing to illness in the family and a further inability on their part to care for him properly, he was taken to the Norristown State Hospital, Jan. 28, 1905; he was then 21 years of age. The records of the hospital at that time, while rather meager, state that he was an idiot and could not talk or walk, had to be fed, was unclean; quiet and did not make any sound. He weighed 65 pounds and was about 4 feet 2 inches in height. His chest was pterygoid in type, the lungs normal, the heart-action regular, but rapid; no murmurs were elicited; the pulse was rapid, but regular; the hands and feet were cold and cyanotic; he had abnormally long arms; the ears were quite large and head was small. He showed atetoid movements of the upper extremities. The muscles of the lower extremities were apparently paralyzed and showed contractures; the knee-reflexes were exaggerated and showed ankle-clonus; the pupils responded to light.

A review of his physical condition a short time before his death, Dec. 20, 1913, showed the following cranial measurements: biparietal, 12 cm.; occipitobregmatic, 13 cm.; occipitomenal, 20 cm., and cranial index 923. The head was covered by a loose thick scalp. The ears were quite large; palate arch high; the arms were rather long and the hands large and coarse. The fingers were heavily calloused from being continually bitten. The musculature of the lower extremities

was poorly developed and showed marked contractures; extremities were cold and cyanotic. The patient's actions were rather jerky. The chest was round with the sternum quite prominent; the left apex showed a cavity formation. The abdomen was apparently normal, while the genitalia were unusually well developed.

In appearance he resembled more closely a monkey than a human being and this led to his being called "the monk"; he might easily have been used as a specimen to carry out the Darwinian theory.

The ward notes as to his mental condition varied but little during his time in the hospital, the substance of them being that he was entirely helpless, unclean in his habits, usually dull, but at times appeared to observe what was going on about him, took no special interest in any one thing, would watch people going about and could be attracted by strange noises such as the dangling of keys, etc., when he would look toward the source of the noise. He was always more or less destructive and would tear his clothing, using both hands in doing so. Frequently would hold the cloth with one hand and tear with the other.

About April, 1913, the ward physician was able to interest several of the other inmates in this patient's condition in an effort to observe just what effect constant personal effort in the patient would bring out. These inmates devoted most of their time to him and would perform all sorts of antics for his amusement. Gradually he appeared to watch them, and would become excited, jump in his chair and laugh at their actions; at times would grunt as if in an effort to speak; he also seemed to know these particular men, for when they would approach him he would become excited, but when a stranger approached he paid no attention and hung his head.

These men would also throw a handkerchief to him and he gradually learned to watch for it, catch it and then throw it back, but without any definite direction; at times they would cover his head with it and he would pull it off and throw it at times with one hand, and again the other, and seemed to wait for them to replace it, apparently enjoying its performance. He would only do these things, however, with the persons with whom he was acquainted. Generally, he became much brighter and watched any moving object and at times would become quite noisy, and this state continued until his final breakdown and death.

Fig. 2.—Lateral view of brain.

Post-mortem Findings.—The head is covered by short thick brown hair. The scalp is thick, average 8 mm., contains much fat, and shows many transverse folds. The epicranium is thick, white and tough. The skull is hard and contains a fair proportion of diploe. It measures 5 mm. in thickness in the frontal region, 2 mm. in the parietal region, 9 mm. in the occipital region. All the sutures are indistinct, in places entirely obliterated. The dura is generally a little thick, but strips from the calvarium readily. The internal measurements of the skull, at level of section, are 10.5 cm. anteroposteriorly, and 8 cm. transversely at the parietal eminences. The anterior basal fossa measures 3 cm. anteroposteriorly, 3 cm. transversely at the widest portion, and is perfectly flat. The

middle fossa measures 5 cm. anteroposteriorly, 3 cm. transversely, 1.5 cm. in depth. The posterior basal fossa measures 3 cm. anteroposteriorly, 4 cm. transversely, and 2 cm. in depth. The pia-arachnoid is slightly opaque over the sulci, and here the subarachnoid space contains an excess of fluid. The brain is extremely small. The posterior lobes do not cover the cerebellum and the latter protrudes 1 cm. behind the occipital pole on the left side and 1.5 cm. on the right side. The cerebral hemispheres measure 9 cm. from frontal to occipital pole and 4 cm. in width. The convolutions are rounded and extremely elementary and vary considerably in width. The fissure of Sylvius is well defined. The posterior limb extends upward and backward, reaching the neighborhood of the great longitudinal fissure just behind the middle of the superior edge of cerebrum. Its course closely resembles that of the normal fissure of Rolando. There is depression at the site of the ascending limb of this fissure. A well-defined fissure lies anterior to the posterior limb of the sylvian fissure on the left side, which probably corresponds to the rolandic fissure. From this, two short fissures run at right angles, probably corresponding roughly to the upper and lower frontal fissures. The right frontal lobe is similarly marked, but less distinctly. The orbital surfaces of the frontal lobes show two short, shallow anteroposterior sulci, separating

Fig. 3.—Looking down in hemispheres. Note absence of corpus callosum.

it into three convolutions. The olfactory bulb and tract are small. The trigonum olfactorium is larger and more distinctly formed than normally. The temporal lobe is rather well defined. Three horizontal fissures run roughly parallel to the sylvian fissure. The superior temporal fissure is well defined. There is a distinct supramarginal and angular gyrus. A small depression probably corresponds to the intraparietal fissure. On the mesial surface of each hemisphere, one irregular sulcus is seen, corresponding to the callosomarginal fissure, which approaches the superior edge of the hemisphere behind the position of the sylvian fissure. No distinct parieto-occipital, calcarine or parallel fissures are found, so that it is impossible to define the mesial and lower aspects of the parietal and occipital lobes. The hippocampal convolution is also poorly defined, but wide. There is one depression in the lower surface of the temporal lobe near the temporal pole. If this marks the width of the uncus, this convolution measures 1.5 cm. in width and is the widest convolution of the brain. Elsewhere the convolutions measure 0.5 to 1 cm. in width.

No corpus callosum connects the hemispheres, the pia-arachnoid of which was slightly adherent. The pia-arachnoid is reflected from one hemisphere to the other, and beneath this a thin membrane, apparently the tela choroidea, is seen. When this is incised the third ventricle is exposed. The fornix is not fused and can be seen over each thalamus, running anteriorly and downward as the descending pillars. The cortex lies close to the fornix above. No anterior horn of the lateral ventricle is apparent and the head of the caudate nucleus is not seen. At the normal position for the foramen of Monro, beneath the descending pillars of the fornix, fringes of the choroidal plexus are found, likewise on the under surface of the velum interpositum, in the midline. The thalami are seen, also the anterior, middle and posterior commissures, the region of the habenular nuclei, a small pineal body, and corpora quadrigemina.

Sections of the right hemisphere show the absence of the anterior horn of the lateral ventricle. The caudate and lenticular nuclei, internal and external capsule, claustrum and optic thalamus are in normal relations. The lenticular nucleus is relatively large. The posterior and inferior horns of the lateral ventricle form one large horn extending from the level of the surface of the optic thalamus. The shelving fornix and the choroidal plexus extend downward into the temporal lobe. A distinct small cornu ammonis is present. The cerebral cortex varies from 2 to 4 mm. in width.

The cerebral peduncles and pons are small, but the whole medulla is relatively large, approaching the normal adult size. The cranial nerves appear at their normal positions and are small, except the third and fifth, which are relatively thick. The pituitary body is relatively large, and of normal size. The circle of Willis and vascular supply are normal.

The cerebellar hemispheres measure 45 cm. anteroposteriorly by 4 cm. transversely. In gross appearance, both the vermis and hemispheres are normally marked and small, but not in proportion to the cerebral hemispheres. The brain weighs 220 gm.

The preceding description is based on a comparison with the normal adult brain. The scale of development, compared to the brain of the monkey and ape has not been sufficiently studied. Dr. E. A. Spitzka states that the brain is as small and elementary in cortical development as he has seen in a human brain. He believes that it has no distinct occipital lobe and agrees that it is incallosal. The cortical development is much below that of the higher apes. A more complete comparative and pathologic study of the brain will be undertaken and reported.

For the preceding report of the necropsy I wish to express my appreciation to Dr. Charles J. Swalm, Pathologist to the State Hospital.

FUNDAMENTAL INTRAPELVIC PERINEORRHAPHY*

ALBERT GOLDSPOHN, M.D.

Professor of Gynecology, Chicago Post-Graduate Medical School; Surgeon in Chief, Evangelical Deaconess Hospital

CHICAGO

Friedrich Schatz¹ in 1883, standing chiefly on the work of Luschka,² it appears, was the first gynecologist to point out in detail the anatomy of the female pelvic floor in general and that of the levator ani in particular, to define its functions and to describe the injuries which it receives, chiefly during parturition, in its posterior, lateral and anterior sections. He makes it clear that injury of the levator ani may occur independently of the perineum (submucous tears), but more usually with tears in the latter, and that truly intrapelvic work is needed to accomplish the best that can practically be done with them. The next most notable promotion of the subject occurred in 1889 by R. L. Dickinson,³ who corrects some misconceptions of the anatomy and presents the results of tests of the contractile power and lifting capacity of the levator ani. The results of these tests I regard as necessarily due partly to the concurrent actions of the bulbocaver-

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

* This article has been abbreviated by the omission of some of the illustrations. The article will appear in full in the Transactions of the Section and the author's reprints.

notus muscles and inner borders of the trigon, that could not be excluded.

Next, Charles P. Noble,⁴ in 1897, published a method in which he made a modified Emmet denudation and passed interrupted sutures transversely, taking in the vaginal wound edges with those of the levators beneath, with the aim to attach the latter to the former rather than to unite the levator borders. After this, in 1901, I⁵ emphatically reiterated the superficial character of all the former standard perineorrhaphies and dwelt on the necessity of utilizing the more

Fig. 3 (Plate 13 of Edward Martin's Atlas).—Labia, skin, subcutaneous fat, superficial perineal fascia and contents of the ischioanal fossae removed. The ischiocavernosus (a), bulbocavernosus (b) and the superficial transverse perineal (c) muscles (belonging to the superficial stratum) are intact on the left side; but the latter two are cut away (d) on the right side to expose the urogenital trigon (e) on that side. The bulbi (f), Bartholin's gland (g), vulva (g), and the anus (h), with the external sphincter (i), are intact. The levator ani (the innermost stratum) is divested of its outer fascia.

deeply seated but available portions of the levator ani and its fasciae, by true intrapelvic operating. I described and illustrated the various steps of an operation performed by myself for six years previously. During the past twelve years, most operators have obviously modified their former methods with an effort to engage the levator ani (with doubtful success), and a goodly number have abandoned their old methods entirely for a new and modern technic, professing to deal with the levator ani efficiently. While this has been achieved by some, in more instances it is evident from their descriptions and illustrations that they have mistaken some more superficial structures for the levator ani. This is one reason why I am again speaking on this subject, after a pause of thirteen years. A second is that recent and greatly superior anatomic studies and publications on the female perineum need to receive more general recognition, and a third reason is that the importance of the fasciae in the woman's perineum and pelvic diaphragm is recognized and emphasized by only few clinicians in their writings. The new and superior anatomic works referred to are by Halban and

Tandler,⁶ W. Liepmann,⁷ Hugo Sellheim⁸ and Edward Martin.⁹ Waldeyer, Holl and Rieffel, whose authority is largely recognized in these newer studies, divide the female perineum and pelvic diaphragm grossly into three layers from within outward:

First, the principal part, a shallow funnel-shaped muscular layer (Fig. 4) composed of coccygeus and levator ani muscles, is invested on the upper or visceral side by a layer of pelvic fascia, called fascia endopelvina by some and rectovesical fascia by Gray; and on its lower or peripheral surface by another layer of pelvic fascia called the ischioanal or anal fascia by Gray, it having a connection with the upper sphincter. This main portion of the pelvic diaphragm is usually clearly shown in most anatomies and particularly in Figure 4. The levator ani is subdivided by some into the ischiococcygeus, ileococcygeus, pubococcygeus and puborectalis muscles. It is the latter that is chiefly engaged in plastic restoration of the injured pelvic floor.

The second layer, the urogenital diaphragm or trigon in the male perineum is clearly set forth in our general anatomies; but in the female perineum it is dismissed with a mere mention of a triangular ligament, but no proper conception at all is given as in the anatomic studies above mentioned (Figs. 2 and 3), that in the female there is also a virile urogenital diaphragm or trigon composed of two potent layers of fascia, the outer one being even aponeurotic, with

Fig. 4 (Martin, Plate XIII).—Chief muscles of the outer stratum or layer and the bulbi removed. The urogenital trigon (the middle stratum) composed of two layers of fascia with muscles between them, is intact on the left side (a), but has the outer aponeurotic layer removed on the right side, to show the fibers of the transversus perinei profundus (b) within. The anus (c), the vulva (d) and the levator ani (e) are intact as before. The crura of the clitoris (f) are shown, the left one in its relation to the ischiocavernosus muscle.

the muscle of the urogenital trigon (or transversus perinei profundus) between them. This composite

fascial and muscular plate, closing the pubic angle formed by the descending rami of the pubis and ascending rami of the ischium, reinforces the levator ani from below. Like the latter, it has a median urogenital aperture whose borders are firmer, more distinct and less yielding than are the borders of the genital cleft of the levator. It composes the trigon in the female perineum, and beneath it lie the subfascial (superficial) muscles—the superficial transversus perinei, the ischiocavernosus and the bulbocavernosus composing the *third layer* (Fig. 2). The bulbocavernosus, surrounding the vulvar opening, reinforces the inner margin of the trigon; and these together are what some operators have mistaken for the levator ani, whose anterior median edges lie farther within, are less distinct and extend more in an inward and upward direction. This mistake is apparent from the illustrations and described technic of Robert T. Morris,¹⁰ Arnold Sturmdorf,¹¹ C. A. Hall,¹² George B. Somers¹³ and C. W. Barrett.¹⁴

Fig. 5 (Martin, Plate XIV).—All the structures of the superficial and of the middle strata removed up to the margins of the rectum (a) and vagina (b), that have been carefully preserved, the latter as a projecting collar, which is surrounded by the remaining edge of fascial trigon (c). The ischioanal fossa have been cleared out and the muscles composing their walls—the levator ani (d), the internal oblique (e) and the pyriformis (f)—have been divested of their fascial covering.

Edward Martin has made some of the best dissections and sections *en masse* of hardened female pelvises under the direction of Waldeyer. Copies of some of his plates are here presented. He says, "The distinct edge which is felt in the vagina is not the levator edge, but the inner border of the urogenital diaphragm," that is, the fascial trigon. The levator ani lies beyond this structure farther within the pelvis, more like a curtain hanging down over the lateral bony walls of the pelvis. The needle or sharp volsellum that picks it and its fasciae up right will sometimes hook into the periosteum beneath it, and will then require releasing a little. These bilaterally receded parts of the levator

that we need to bring together and unite in the median line back of the vagina and in front of the rectum always lie from 4 to 5 cm. or more away from the muco-skin junction, where the operation begins; and their efficient union requires that a flap of posterior

Fig. 6 (Martin, Plate XV).—Section showing the three main strata of the structures in the female pelvic floor, and the three layers of the trigon (middle stratum); a, superficial fascia; b, superficial transversus perinei muscle, and c, sections of bulbocavernosus and ischiocavernosus muscles, composing the outer stratum; d, the outer fascia (aponeurosis) of the trigon; e, inner fascia of the trigon; f, transversus perinei profundus muscle lying between these fasciae and completing the trigon (middle stratum); g, the levator ani, the innermost and chief stratum.

Fig. 9.—The posterior vaginal wall must be raised to a distance of from 7 to 8 cm. inward, and laterally to the level of the white line in the pelvic fascia of each side.

vaginal wall be raised extending from that line inward at least 6 to 8 cm. and laterally near to the arcus tendineus or white line in the pelvic fascia. These deep-seated receded parts of the levator ani with its fasciae are best caught up on each side and drawn

toward the median line preliminary for suturing, by curved volsellum forceps with semisharp teeth, so as to avoid puncturing hemorrhoidal veins unnecessarily, the rectum being held out of the way by the index-finger of the left hand.

Union of these parts thus brought into view is made by three or four turns of continuous or interrupted strong sutures of catgut chromicized or treated with formaldehyd, the third and fourth of which and all succeeding sutures catch enough of the areolar tissue over the rectum below and beneath the vaginal flap above to obliterate the dead spaces and to gather the broad vaginal flap into small anteroposterior folds and to fasten it sufficiently on top of the newly made bridge of levator beneath. The fasciae of the levator are really the most important part in the bridge, as its comparative inelasticity shows when it is thoroughly made. All of this bridge, if it is really composed of levator ani, will be within the pelvis beyond the more prominent and palpable ridges or strands that are commonly felt in the perineum passing up along the sides of the lower section of the vagina.

As the suturing of the wound continues from the bridge mentioned above downward, these inner edges of the fascial trigon, as the second layer in the pelvic floor, are also united, and likewise the bulbocavernosus and transversus perinei muscles (of the third layer) that should coalesce in the tendinous center of the outer perineum in front of the rectum. The technic of the operation in detail is shown in the illustrations. Suffice it to say that the buried sutures, whether interrupted or continuous (with a tie at every third or fourth turn), should not penetrate the vaginal flap,

Fig. 10.—The corresponding portions of the levator ani with its fasciae are each caught up from the bony walls of the pelvis at a depth of from 5 to 8 cm. within, by a semisharp volsellum forceps curved sidewise. They are approximated and separately united near the median line, by three or four interrupted or continuous strong catgut sutures.

but merely catch into the submucous tissues beneath it. No figure-of-eight sutures should be employed anywhere in this operation.

In cases of complete tear through the sphincter ani, the operation, first suggested by a German for this injury, is first performed as follows: A shallow inci-

sion varying in outline between an inverted V and a semicircle is made from a little outside of the point of retracted sphincter end of one side to the corresponding point or sphincter end on the other side, and at a distance of from 1.5 to 2 cm. away from the edge of the tear in the rectum. From this curved line downward to the border of the tear a thin flap is very carefully dissected up without perforations, and turned downward over the cleft in the sphincter and rectum

Fig. 11.—After the levator has been sutured separately, the remaining wound is closed from side to side, from within outward, by continuous catgut sutures passed circuitously and knotted at every third or fourth turn, and the skin wound is closed vertically by interrupted silkworm-gut sutures.

to protect all sutures from contact with the bowel lumen or its mucous membrane. The raw surfaces and exposed ends of torn sphincter are then brought and united together by interrupted catgut sutures, over the raw surface of the flap. It is well to place a silkworm-gut suture in the rectovaginal septum beyond the first incision to relieve the tension on the other sutures.

2120 Cleveland Avenue.

CHIEF FACTORS IN FAILURE OF OPERATIONS FOR RETRODISPLACEMENT OF THE UTERUS*

FREDERICK C. HOLDEN, M.D.

Attending Obstetrician, Methodist Episcopal Hospital; Assistant Attending Obstetrician and Gynecologist, Long Island College Hospital, and Lecturer on Obstetrics and Gynecology, Long Island College

BROOKLYN

This paper makes no pretense to novelty. It is just an emphasis on things said before. I like to ask "why," to dig up causes and to handle them with bare hands, and so I present just a few facts, recall a few failures and make a few suggestions.

First, the facts. They are alphabetic, but one needs initials to spell so big a word as "success."

* Read before the Section on Obstetrics, Gynecology and Surgery at the Sixty-Fifth Annual Session of the Association, Atlantic City, N. J., June, 1914.

I. ANATOMIC FACTS

The first group of facts is anatomic.

1. The normal uterus is a freely movable organ and is suspended in the pelvis between the abdominal cavity and the pelvic floor by the harmonious action of its several supports, that is, (a), the pelvic floor; (b), the adjacent pelvic organs; (c), the retentive power of the abdominal cavity; (d), the several ligaments, and (e), the normal relation which the uterine axis bears to the axis of the vagina.

In the erect posture of the woman, bladder and rectum being empty, the os externum is in the plane of the ischial spines, or a little below it and slightly posterior to a central position in the pelvis. The cervix projects into the vagina and is directed toward the last sacral vertebra, and is held in this position by the uteropelvic and the uterosacral ligaments, and the vesicovaginal fascial plate. The upper and posterior aspect of the fundus is at or a little above the level of the plane of the brim. The axis of the uterus is at nearly a right angle with that of the vagina, the body resting on the pubic (fascial) shelf.

The axis of the uterus has a wide range of inclination dependent on the degree of fulness of the bladder and rectum. With bladder and rectum moderately full the uterine axis conforms to the axis of the pelvis. With the bladder empty the axis of the vagina is almost horizontal and runs almost directly backward, while the uterus is directed forward at an acute angle and is in a position of marked anteversion, slightly ante-flexed. The attachments of the uterus are for the most part of yielding character which allows great freedom of motion in all directions, rising and falling with the respiratory movements and changing its position with the different positions of the body. A full rectum pushes the uterus bodily forward and a full bladder displaces it backward.

The ligamentous supports of the uterus are the round ligaments, muscular bands covered with peritoneum which tend to hold the fundus forward, acting as "guy-ropes" to prevent it from falling backward.

The uteropelvic ligaments, which consist of bands of muscle-fibers running outward from the supravaginal portion of the cervix to the pelvic fascia within the base of each broad ligament, prevent the uterus from undergoing lateral changes in position and help to sustain it in its proper plane.

The broad ligaments, which act in some measure to steady the uterus in or near the median section of the pelvis, and the uterosacral ligaments made up of muscle and cellular tissue and covered with peritoneum, pull the cervix upward and backward and prevent its downward displacement.

The pelvic floor, which preserves the position and integrity of all of the organs and soft parts of the pelvis, indirectly supports the uterus. The pelvic floor, the uterosacral ligaments and the uteropelvic ligaments are the chief supports against downward displacement.

These facts are recalled mainly to rivet our attention on this fundamental fact—that nature has provided women with these ligaments and supports for certain definite purposes, and when such supports and position are at fault it is the duty of the gynecologist to determine before operation what are the digressions from the normal.

II. HISTORICAL FACTS

The second group of facts is historic. The pioneer work in this department of gynecology was done by

Alquié about 1840. More than a quarter of a century afterward came Koeberle, 1869; Adams, 1880. The real work in this line, however, originated with Alexander, when in 1881 he performed his first operation, reports of which he published in 1884. In 1886, Kelly and Ohlshausen devised intra-abdominal operations for suspension of the fundus. Wylie, in 1886, intra-abdominally shortened the round ligaments for retro-deviation, and reported his cases in 1888-9; and in 1889 Freund shortened the uterosacral ligaments. More recently we have plication of the round and broad ligaments after the method of Coffey; also plication of the vaginal wall after the method of Emmet-Baldwin.

These were the pathfinders in our specialty, and although there have been a multitude who, since their work, have cried "lo! here" or "lo! there," I am persuaded that every procedure in operating for retro-displacement is only a modification or adaptation of the procedure of one of these six primary methods.

III. FAILURES

And now as to the failures; but why speak of failures? Because, they are facts, big, bulky facts which ought not to be, and again because they are our most efficient if not our most delightful teachers. In the world of economics the word to conjure with to-day is "efficiency," and as we analyze the curriculums of the schools of commerce where this new science is being studied, we discover that the student is taught that waste is worth while, that every failure has a cash value. Let us liquidate ours and we have a goodly asset in this department of surgery. The proportion of failures was brought very forcibly to my attention at a recent meeting of the New York Obstetrical Society, at which time a symposium was held on "The End Results of Operations for Retrodisplacement within the Last Five Years," done by different notable gynecologists at the various hospitals in Greater New York. A summary of the results of this symposium is soon to be published in the *American Journal of Obstetrics*.

And now what is the cause of our failures? First, a plain neglect of the alphabetic facts of anatomy such as I have summarized above, a failure to take counsel with Nature's simple physiologic mechanics. Secondly, what might be called a passion for originality, in which the enthusiastic operator permits himself to be obsessed with his own idea to the forgetfulness of the work done by the pathfinders in our department.

The following points should be passed on before determining what shall be the operative procedure in a given case:

1. What is the age of the patient? If the woman is in the child-bearing period, no operative procedure should be undertaken which will cause any interference with pregnancy; whereas, if the woman is past the menopause, the simplest operative procedures which will hold the cervix upward and backward and the fundus forward should be undertaken.

2. What is the condition of the pelvic floor? It is trite to say that it is absolutely essential that a corrected or overcorrected pelvic floor of a firm muscular type, as for instance an Emmet-Holden, must accompany any operative procedures for retrodisplacement when there is a relaxed pelvic floor existing.

3. What is the position of the cervix, and can it be replaced up in the hollow of the sacrum? It has been interesting within the last year or so in Dr. Polak's Clinic at Long Island College Hospital, to see

the number of cases in which we have not, on discharge of the patients from the hospital, found the uterus in an anatomically perfect position. On investigation we have almost universally satisfied ourselves that the reason for such disappointment has been that we had a cervix which did not go backward when the fundus has been brought forward by the operation which we had selected for the given case, and on further observation we are satisfied that in these cases we have not achieved the desired result, because we did not appreciate the fact that there was a congenital short anterior invagination of the cervix which prevented it from taking its normal position, even though there was a firm pelvic floor and the fundus was brought well forward. Such cases we have time and time again seen recur. It is the information gained from this particular type of case which stimulated me to thought with reference to failures, and if possible by analysis to minimize my own failures.

Reynolds, in his original article "Anteflexion of the Cervix and Spasm of the Uterine Ligaments in Relation to Retroversion, Dysmenorrhea and Sterility," dated May, 1911, read before the American Gynecological Society, called attention, in connection with the treatment of sterility, to the advantage to be gained by lengthening the anterior vaginal wall and thereby allowing the cervix to be placed in normal position. I am of the opinion that Reynolds' article has not received the attention of which it was worthy, and so the facts of his procedure have not been appropriated to the correction of retrodisplacement of the uterus. With this idea in view I have tried to emphasize the advantages to be gained by the Reynolds' operation in conjunction with other operative procedures. I say advisedly that long ago the pioneers in this department of surgery laid it down as primary that, it matters not how far forward or by what method the fundus is brought anteriorly, cases will recur if the cervix is not placed upward and backward in the hollow of the sacrum, and my own observation goes far to commit me unqualifiedly to the same conclusion.

To be practically specific and illustrate the reasons for frequent failure, I mention the following complications and failures in some of the well-known methods which we have used:

1. The Webster-Baldy operations: Two tubal pregnancies due to angular constriction of the tube in its isthmic portion arresting the impregnated ovum in its transit to the uterus.

2. Lateral version of the uterus, due either to unequal primary development of the ligament, present but unnoticed or unappreciated at the time of operation, or to torsion of the ligament from defective technic.

3. Large ovaries slung over the encircling band formed by the round ligaments tend to fall low in the pelvis by lengthening of the utero-ovarian ligament, and become adherent to the posterior surface of the uterus or broad ligament.

4. The sigmoid may become adherent to the ligamentous loops, causing left-sided pain and digestive disorders.

5. The ligaments passed behind the uterus may become edematous from constriction and offer an inflammatory surface for intestinal adhesions.

6. Ovarian enlargement as a result of venous stasis of the broad ligaments.

7. A large uterus may sink in the pelvis through the encircling ligamentous loop and the ovaries are

carried upward and to the median line and thereby become adherent to one another, forming a sensitive mass on the posterior wall of the uterus.

In the 437 Webster-Baldy operations performed by Polak and his associates, twenty-six patients had thrombosis of the pelvic veins, which had extended to the femoral and saphenous. The type of cases in which we have used this operation successfully is that in which there is a small uterus and two well-developed round ligaments.

Coffey plications of the round ligaments have been followed by the following complications: exudates in the uterovesical space and painful uteri with limited motion. Dyspareunia has been one of the chief complaints.

In the two cases in which the abdomen was reopened the pathology was interesting; in one the uterus was prolapsed and hanging from the anterior vaginal wall by two ribbon-like bands, the round ligament was not appreciable, being similar to those bands found after simple ventrosuspension, while in the other case the uterus was buried in adhesions.

This operation is useful in covering over raw surfaces on the anterior uterine wall after myomectomy, etc., in conjunction with a uterus which tends to sag backward.

The chief objection we have found in the operation is that it brings the whole organ forward in the pelvis yet does not exaggerate the anteversion and subsequently the cervix slides up under the symphysis followed by the backward displacement of the fundus.

We have had a number of failures by the Gilliam, and the Montgomery-Gilliam, for the reason that the cervix is not carried up into the hollow of the sacrum.

When prolapse is associated with retrodisplacement in a woman near or at the menopause the transposition operation has been very satisfactory. The Emmet-Baldwin plication of the anterior vaginal wall has been done very seldom but is considered a very satisfactory procedure because it places the cervix well backward and upward.

IV. CONCLUSIONS

It is obvious that I have only gleaned in the field which stretches to the horizon of surgery, but this much grain may be gathered from what I have gleaned.

1. The gynecologist must be strong in the grace of discriminating; he must receive as alphabetic the proposition that the cervix must be placed upward and backward in the hollow of the sacrum.

2. No one operation already devised or to be devised will cure all sorts and conditions of cases. As individual as is the patient, so individual may be the patient's displacement, and this element of individuality must be seen clearly and bulk large in the operator's diagnosis—hence, the absolute necessity for the fundamental grace of discrimination.

I beg leave to report a personal interview which I had with an operator of note two years ago, at which time I asked the following question, "Do you do your operation on all cases of retrodisplacement of the uterus?" and the answer was in the affirmative.

The gynecologist must possess in a great degree the grace of self-elimination. The passion for spurious originality must be brought to heel like a well-broken dog. In my opinion the six procedures recalled in the historical survey, with the addition of the Reynolds operation in those cases in which a short anterior invagination of the cervix exists, present a sufficient

number of points of departure for, loosely speaking, every case. Given an intelligent appreciation of the essential element in each one of these six alphabetic procedures one is on the line of approach to the cure of every case.

3. Adaptation, modification and synthesis. Having made his selection of the main procedure it remains only for the operator to apply that procedure which with its individual modifications is called for by the case before him. The opportunity for modification is infinite, as various as the cases themselves. The modification may consist of an exclusive use of one of the main procedures, or by synthesis of the whole or part of two or more of the main procedures. In short, success in this particular operative field, and that must always mean success for the individual patient, is to be achieved by an unqualified commitment to fundamental anatomic facts, by elimination of self and by adaptation of existing procedures to individual cases by a process of modification and synthesis.

158 Lincoln Place.

ABSTRACT OF DISCUSSION

ON PAPERS OF ERS. GOLDSPOHN AND HOLDEN

DR. GEORGE R. WHITE, Savannah, Ga.: Our failures in these cases, whether they be of retroversion or prolapse—the two conditions are very closely associated—are because we do not take cognizance of natural methods. I disagree with Dr. Holden in placing the emphasis on the anatomic parts. It has been mentioned that the perineum supports the uterus; the uterus stays up as well when the perineum is cut right through. The uterosacral ligament is not much of a factor. The emphasis should be placed on the uteropubic ligaments, the so-called cardinal ligaments. The easiest way to do the operation is to make a small incision in the broad ligament, opening it up fully and putting in a retractor. Down under the coronary ligaments are the supports of the ligament, and there the deviations of the uterus may be straightened. The tissues here are strong and firm and will hold during pregnancy. Operation is done in different ways, by the Marcy operation, by the adnexal operation, etc. Both operations are good and either can be done if the ligaments have not broken loose by a difficult delivery and become contracted in the side of the pelvis. To get at them one must come down over the broad ligament and pull them out until reaching firm tissue; then use them where they belong. On that line I believe we shall make our advance in the treatment of retrodisplacement and prolapse.

DR. H. GRAD, New York: I was glad to hear Dr. Holden's paper because it deals with the failures. Dr. Holden referred to the papers on Retroversion of the Uterus, which were written for the New York Obstetrical Society, and I had the pleasure of looking up the operation for retroversion in one of our hospitals. I found that at the Woman's Hospital about 800 women had been operated on in five years. Only a small number of these could be traced. The studies of the cases that could be traced showed that no matter what method of operation was employed for the uncomplicated cases of retroversion, success was obtained in about the same proportion of cases. Anatomic results were obtained in a large number of cases. The symptomatic results in the Alexander operation were about the same as in the Gilliam operation, almost the same as in ventrosuspension. It seemed to make little difference what operation was done in the uncomplicated cases of retroversion. It makes no difference whether one plicates the round ligament or cuts the broad ligament and stitches it together, they all give about the same result. The trouble comes when complications enter, when the cervix has fallen down, when the cardinal ligaments which Dr. White spoke of have retracted and allowed the pelvic floor to sink. In these cases failures will follow. A large proportion are due to the fact that the anterior wall

of the vagina is short, as Dr. Holden pointed out. Here we must treat the complications. Dr. White said that the uterosacral ligaments did not give much support to the uterus. This may be true, but when one utilizes them in operations they give good results. About three years ago Dr. Jellet of Dublin published reports of twenty cases in which the uterosacral ligaments were used. Since that time we have been using the method of shortening the uterosacral ligaments in complicated cases in which the pelvic floor has been split and with excellent results. It is of first importance, therefore, to distinguish between lacerations of the perineum and of the pelvic floor, as laceration confined to the perineum is always a laceration in the median line. If superficial it will give rise to but few or no symptoms, but if deep enough it will separate the transversus perinei muscles which coalesce at this point with other muscular structures and by retraction of their torn ends will cause a gaping vulvar orifice. When, as is usual, both of these anatomic structures are involved, the laceration of the perineum being central and that of the pelvic floor lateral, it is of first importance to make the dissection not alone within the vagina to restore the pelvic floor, but likewise to carry it down low enough so that the retracted transversus perinei muscles can be included with the overlying fascia and sutured at the same time the pelvic floor is repaired.

DR. JOHN M. FISHER, Philadelphia: Dr. Goldspohn very properly calls attention to the fact that in order to appreciate the symptomatology and clinical significance, as well as the operative procedure adapted to the proper repair of the pelvic floor, it is of first importance to have a clear conception of the anatomy of the parts. Evidently he has not read the article on Diseases of the Vulva and Vagina in Keen's Surgery, volume 5, in which I described minutely the very thing to which he calls attention, the triangular ligament, or as I term it, the vaginal septum. In the study of vulvovaginal injuries we must take into consideration this triangular ligament in its relation to the muscular structures of the vulva. If this is not done, especially in operating on the pelvic floor alone when there has been laceration of the perineum in addition, we still have to deal with a gaping vulvar orifice.

DR. C. M. ECHOLS, Milwaukee: A word about the Reynold's operation which Dr. Holden has had occasion to do. I have been looking for indications during the last year to do this operation but very rarely have found a suitable patient, especially among multiparous women, who constitute the majority of patients on whom we have to operate. Most of these women I have to operate on have a little tendency to cystocele, and the Reynold's operation is contra-indicated in all such cases.

DR. JOHN A. MCGINN, Philadelphia: In the matter of the history of the operation referred to as the Reynolds operation, Dr. B. F. Baer of Philadelphia did this operation at the same time as Dr. Reynolds, and I feel that it really deserves to be termed the Reynolds-Baer operation.

DR. CHANNING W. BARRETT, Chicago: Dr. Goldspohn and I agree that the importance of this question lies in the fact that perineal work is in the developmental process instead of a finished condition. He laid stress on the inefficiency of many of the standard cardinal operations, and I agree with him thoroughly. Dr. Goldspohn did pioneer work some years ago, but he stopped by getting deep enough, and then, instead of isolating muscles and fascia—and he gives the reason for that—he left it at that point, closing by side to side sutures. I emphasize the point that this is mural work, dealing with the lower wall of the abdomen, and that it is hernioplasty. Several years ago, having a condition of this kind, I devised a procedure of making a longitudinal incision posteriorly and closing it transversely.

DR. BROOKE M. ANSPACH, Philadelphia: The attention which has been given in recent years in perineorrhaphy to the dissection and coaptation of the actual fibers of the levator ani muscle and the deep layers of the pelvic fascia, has undoubtedly improved the results of the operation. In all operations of this type, it is desirable to place some sutures in such a fashion that the anterior wall of the rectum is

drawn well up toward the cervix. Dr. Ward of New York has laid stress on this point. It is undesirable in these operations to remove any more than a minimum amount of the vaginal mucous membrane. If the vaginal mucosa is extensively removed in the denudation and dissection preceding the introduction of sutures, the redundancy of the vaginal wall which nature has provided in the vaginal sulci is lost, and a repetition of the laceration in subsequent childbirth is almost inevitable.

DR. ALBERT GOLDSPOHN, Chicago: I am convinced that many gentlemen who are not dealing with the levator ani in their operations think that they are. They are honest about it but they are mistaken. While Dr. Barrett may now be going deep enough to seize the levator, he has repeatedly mistaken the inner edges of the trigon and bulbocavernosus muscle as the levator ani muscle in his illustrations. Edward Martin says in his new Atlas, "*Haftapparat der Weiblichen Genitalien*" that this is a common clinical mistake. With regard to the remark of Dr. Fischer, concerning the article in Keen's Surgery, no proper conception at all is there given of the urogenital trigon—a three-ply structure—as constituting the most tangible, the middle stratum, of the female perineum. Waldyer's division of the female pelvic floor and perineum into three strata, makes the anatomy much clearer. What has been mistaken, by many operators for the levator ani, is the prominent vaginal edge of the fascial trigon (of the second stratum) reinforced by the bulbocavernosus muscle. These two together can be felt as a firmer structure than the levator ani ever is, at both sides of the vaginal entrance to the pelvis; but they lie more superficially, about in a plane extending between the pubic rami and only about 2 to 3 cm. from the skin border; while the levator lies within the pelvis, more laterally and at twice that depth.

In retroversion work we should choose methods that are anatomically correct. Any procedure that consists in doubling up the thick uterine end of the round ligament in the shortening process, and then depends on the terminal frayed-out useless peripheral end of the ligament to do any holding, is anatomically irrational; not only because the round ligament is so diminutive there, but also, it has no attachment or anchorage outside of the parietal peritoneum, except areolar tissue in its curved course to the inguinal canal. It will yield indefinitely to any pull that is sufficient to dislodge the parietal peritoneum. The Webster-Baldy and the Emil Ries' operations, therefore, I regard as inconsistent on anatomic grounds. Very much better are attempts to get at and to cross the sacro-uterine ligaments in front of the cervix, by way of the vagina. Retroversion is most efficiently dealt with by some transplantation of the round ligament into the abdominal wall, in some one of ten or more different ways. Even in cases in which perhaps it is not ideally the best thing theoretically, practically it is the best thing, because we make use of the thick end of the round ligament to do service; and because this type of operations has borne a good clinical test.

DR. FREDERICK C. HOLDEN, New York: My main object was to emphasize the importance of the proper selection of cases and of operations. Many men are doing one operation in all cases. They may not know that they get failures, but I think others find them. I would say to Dr. McGlenn that I did not mean to rob Philadelphia of any of the glory in the Wylie-Baer operation. I knew that Drs. Wylie and Baer were doing this work simultaneously, but I believe Dr. Wylie was the first to report his results. We do not do the Reynolds operation in the presence of cystocele.

Physical Examinations and Efficiency.—We are already beginning correctly to evaluate the importance of periodic physical examinations in maintaining a continuous state of physical efficiency. Whenever these have been carried into effect, they have resulted in the detection of numerous defects, or diseases, in their incipency, and made it possible to apply suitable remedies before irretrievable damage has been done.—J. W. Schereschewsky, *Public Health Rep.*

ENUCLEATION WITH TRANSPLANTATION OF FAT INTO THE ORBIT *

EDWARD STIEREN, M.D.

PITTSBURGH

The loss of an eye is to any one a dire calamity, but to the laborer or artisan it has its economic side as

well, since employers are usually adverse to giving employment to a man who possesses but one eye.

* Read before the Section on Ophthalmology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

It becomes our duty therefore when called on to remove an eye to provide for a cosmetic after-result that will simulate as nearly as possible a normal appearance, and to strive not only for mobility of the artificial eye but to provide as well a sufficient cushion

Figure 4.

or stump for it to rest on and thus do away with the tell-tale depression of the upper lid, so conspicuous in simple enucleations.

For the past two years and a half I have transplanted fat into the orbit in all of my cases of enucleation, sixty-six in all.

Fig. 5.—In this and Figure 6, cases selected at random from the last twenty-six illustrate the adaptability of the operation to all conditions requiring enucleation. 1. Left eye, exudative iridocyclitis with increased tension; eye blind and painful. 2. Right eye, phthisis bulbi following penetrating injury through cornea and ciliary region. 3. Left eye, absolute glaucoma.

In the last twenty-six cases I have departed from the usual technic as originally proposed by Barraquer, since with it I noticed too frequently a shrinkage of

the cushion from absorption of the fat. I reasoned that the old technic which required the fat to be enclosed within Tenon's capsule provided for entirely too little fat, and also that the fat was not favorably placed to secure the best nourishment. The success with the improved technic, which calls for a much larger piece of fat and direct union of the fat to the conjunctiva, has been most gratifying.

I divide the conjunctiva close to the limbus; dissecting it and Tenon's capsule back as far as possible. A strabismus hook is then introduced under the superior rectus, which is held by an assistant while a double-armed No. 00 twenty-day chromic catgut suture is passed through the muscle from below upward close to its lateral margins behind the hook and loosely tied on top. The suture is then passed through the con-

Fig. 6.—4. Left eye, melanosis of choroid. 5. Right eye, incised wound through upper lid, cornea and sclera; lid sutured and eye enucleated with transplantation of fat at the same time; mobility good, but upper lid thickened and stiff from scar. 6. Right eye, large opaque staphyloma of cornea.

conjunctiva about 2 mm. from its edge directly over the muscle; it is not tied at this time, but only disarmed and the ends held in a pair of hemostats. The internal, inferior and external recti muscles with their overlying conjunctiva are similarly treated (Fig. 1). The eyeball is then forced out of the socket by pressing the speculum backward, drawn toward the nose, and the optic nerve severed. The oblique muscles and any adherent tissues are severed and the socket turned over to an assistant, who, making gentle traction on the four catgut sutures and retracting the conjunctiva and muscles, checks the hemorrhage by packing the cavity with hot moist boric acid cotton compresses.

The abdomen, which has been prepared previously, is now bared and a vertical incision is made in the median line beginning just below the umbilicus and carried downward about 2 inches, cutting through to the aponeurosis of the rectus abdominalis. At the bottom of this incision a similar one is made at right angles and a flap dissected which contains the full thickness of the abdominal fat. A piece of fat which should include the subcutaneous tissue and which should be *about the size of the enucleated eye* is then excised. The abdominal wound is turned over to a second assistant who checks hemorrhage and sutures the integument. The excised mass of fat is then introduced into the orbit (hemorrhage from which is usually checked by this time) *with the subcutaneous tissue upward*, so as to provide for union between it and the edges of the severed ocular muscles and conjunctiva. The catgut sutures are then tied together, traction is made on them and a purse-string suture of No. 0 twenty-day chromic catgut is passed through the conjunctiva and firmly tied (Figs. 2 and 3). Figure 4 shows the appearance of the stump three weeks later, after absorption of the sutures. I allow wearing of the prosthesis as soon as this occurs.

There is no reaction following the operation; the lids do not become swollen or ecchymosed, the only precaution which I insist on being to fill the eye with my modification of White's ointment¹ after the operation and daily thereafter for a week. The time required in the operation is usually about thirty minutes.

There will result a certain amount of absorption of the fat, varying from a third to a quarter of its bulk; but this usually ceases within six weeks after the operation, leaving a soft, mobile cushion on which the ordinary Snellen eye rests comfortably and moves with the sound eye.

Westinghouse Building.

ABSTRACT OF DISCUSSION

DR. JOHN A. DONOVAN, Butte: Some years ago the British Ophthalmological Society appointed a committee to investigate and report on enucleation operations. If my memory is correct, they spent three years careful study and at the end of that time reported in favor of complete enucleation of the eyeball, stitching the tendons together and using the Snellen reform eye. Though I have in season and out of season, preached against so many enucleations yet we have not yet reached the place at which it has become an obsolete operation, so we consider first the safest method, then that giving best cosmetic results. I must admit I have, as a rule, been very well satisfied with the operation as approved by the British Society. Stieren's operation when it is properly performed as far as the eye is concerned appears to be perfectly safe and probably does correct considerable of the cosmetic results of enucleation; this undoubtedly has good features. Though it, in my opinion, entails an extra operation on the abdomen—this though slight, adds a slightly greater risk—this replaced

tissue also must conform to all the requirements of surgical perfection thus entailing again some risk within the orbital cavity. All of which I do not feel, considering the very good results obtained otherwise, to be at all times justifiable. Of course, in infected cases, as most cases are, I presume Dr. Stieren himself does not recommend it. In the operation I prefer to fix each tendon in a curved advancement forceps, cut it and leave it in the forceps till all are cut, then, after removing the globe, stitch these tendons and conjunctiva together by through-and-through suture. This method saves considerable time over that of inserting the stitch in each when reached. I put in a Snellen eye about the fifth day and change its size in a few weeks. I consider the early and constant wearing of a full-sized eye one of the essentials to a neat, successful termination.

DR. JOHN GREEN, JR., St. Louis: An implantation operation has a primary and a secondary object: first, to form a prominent and mobile stump, which shall impart some of its mobility to the prosthesis; second, to produce a socket which shall be shaped to promote and not hinder the drainage of tears and mucus. A mild degree of conjunctival irritation due to contact between the glass eye and mucosa is the rule. After simple enucleation the secretion almost invariably finds its way behind the prosthesis and sinks to the bottom of the socket, there to form a medium for the cultivation of micro-organisms. The Frost-Lang operation, namely, the implantation of a hard sphere of glass, platinum or gold into Tenon's capsule, seems best to meet the indications. Fox, and more recently Sweet and Greenwood, have warmly endorsed this procedure. The latter's experience has led him to adopt a larger sphere than hitherto used. With the sutures disposed in three layers a purse string around Tenon's capsule, muscle sutures, and continuous conjunctival stitches—there is hardly any danger of extrusion. The appearance of the patient after this operation is all that could be desired. Mobility is excellent, there is no depression of the upper lid, and drainage of secretions toward the lid margin is promoted. Some may be deterred from performing this operation by the fear of sympathetic ophthalmia, but, as has been shown by both Sweet and Greenwood, this fear is groundless. Dr. Stieren believes that after a little primary shrinking the implanted fatty mass retains its volume indefinitely. Is such an assumption justifiable? Is it not a fact that after simple enucleation the orbital fat slowly becomes less in volume, the process of shrinkage covering several years, and that which appears after, say, two years, to be a fair result, is shown after five or more years to be a deep cavity into which we place an artificial eye that deceives no one as to its artificiality. Dr. Stieren's oldest cases date back only two and a half years. What will be the appearance of the socket in, say, two and a half years more? Let us not forget too that with advancing years much of the body fat disappears. Is it reasonable to suppose that the implanted fat will be exempt from this process? When cosmetic considerations are of prime importance, I believe the Frost-Lang operation as modified by Greenwood is the operation of choice.

DR. W. E. LAMBERT, New York: I have had a limited experience with this operation, and the immediate result has been satisfactory. I have not been able, however, to follow them up. My impression is that it is not permanent. Has Dr. Stieren followed up his cases, and what is the permanent result? What is his experience with secondary implantation, putting the fat in two, three, or four months after the enucleation? That is being practiced by some and they make great claims for it. I am doubtful as to its being an efficient or a wise operation.

DR. EDWARD B. HECKEL, Pittsburgh, Pa.: I have done a number of fat implantations or transplantations and have come to the conclusion that it is a case of "love's labor lost." I think if we will stop to consider the mechanics of the movements of the artificial eye, our ideas will change as to trying to produce an artificial stump to take the place of the enucleated eyeball. In the case of an eyeball the movements are brought about by a pull, in the artificial eye it is a matter of a shove. The artificial eye moves because the tissues on one side are withdrawn and the tissues on the other side are shoved so that when the artificial eye moves out it does so because it is shoved out, and down because it is shoved down,

1. As I stated in an article on "The Treatment of Ulcer of the Cornea," (Pennsylvania Med. Jour., June, 1907), I have modified and I believe improved the formula originally suggested by Dr. White of Richmond by adding a small amount of lanolin in which to dissolve and work up the mercuric chlorid and sodium chlorid, as follows:

Hydrargyri chloridi corrosivi	gr. i
Sodii chloridi	gr. v
Adeps lanae hydrosoi	q.s.
Petrolati	3 vi

The sodium chlorid and mercuric chlorid are dissolved and rubbed up in about 1 dram of lanolin; the petrolatum is boiled for five minutes, the impregnated lanolin added and, after boiling for five minutes longer, the liquid ointment is poured into jars. After it has cooled it will be found to be of a proper consistency to introduce under the lids, becoming slowly melted by the heat of the body and permeating to all parts of the conjunctival sac.

etc. To get the greatest mechanical advantage for these movements the muscles should be spread apart and not bound together about a small ball of fat or what not. I much prefer to do a simple enucleation without any sutures. After the eyeball has been removed and the bleeding stopped, I allow the lids to collapse and place over them a small roll of sterile gauze about as large as my little finger and cover all with a tight bandage, which is permitted to remain in place for seventy-two hours or even longer. By this method the recti muscles are forced apart and find attachment in the stump where the mechanical advantages for the movements of the artificial eye are greatest. My results for motility of the artificial eye are excellent.

DR. EDWARD STIEREN, Pittsburgh: I am opposed to all implantation operations; I mean the introduction of any foreign substance, as a glass ball. I believe it is surgically incorrect. I make a distinction between implantation and transplantation, as of autogenous fat. With regard to Dr. Green's question, whether the results are permanent, my experience extends over three years now. The case of staphyloma illustrated by Figure 6 was done over two years ago. The picture was taken just before the paper was sent in last March. The mass of fat is still as good. There will be a certain amount of shrinking, probably one-third. Time will tell whether this is a satisfactory operation with permanent results. I am so pleased with it that I shall go on with it. I have had no experience with late transplantation. At the last meeting of the American Ophthalmological Society, Dr. A. N. Alling, who reported two cases in 1910, said to me that he thought the mobility would be as great if the four recti muscles were not sutured together. I tried it since then in one case and the result was disappointing. While the cushion is satisfactory, still the mobility of the eye is poor. I find that to fix the implanted fat thoroughly to the conjunctiva helps to nourish the fat.

REPORT OF A CASE SIMULATING ELEPHANTIASIS*

PAUL W. HOWLE, M.D.

Instructor in Gynecology and Associate in Surgery, Medical College of Virginia

RICHMOND, VA.

History.—M. D., colored woman, aged 29, single, factory-hand, came under my observation at my clinic at the Richmond City Jail Hospital in February, 1913. Her father had died of prostatic enlargement; her mother was living and in good health, aged 45; one brother and one sister had died in infancy. The patient had had the diseases of childhood, and with the exception of an attack of malaria at 16 years of age, had never otherwise been sick. Menstruation began when she was 12 years of age, and was regular and normal in amount until the patient was 21, when it became irregular, appearing frequently twice a month and lasting as long as seven days. For the past year it had been scanty, lasting only three days, and accompanied with a great deal of pain which was usually worse on the last day, at which time she would expel a clot. The patient uses alcohol, drinks tea and coffee, uses tobacco, and probably is a prostitute, though she denies the history of any venereal disease.

Present Illness.—About three months prior to this time, February, 1913, the patient noticed a swelling of each labium which was not painful, but itched continually. The right labium began to swell about one week before the left, and then both increased in size very rapidly for two months, after which time there was little change noted. Coincident with the time that their growth checked, there appeared on the right labium, or anterior growth, an ulcerated area, accompanied by a profuse lymphorrhea. The left, or posterior growth, was painful at times, and the patient suffered with a pain in her back and an uneasy feeling in the tumors.

Physical Findings.—Pendulous growths were noted from each labium which hung almost to the knees when the patient

was standing, the one from the right labium hanging in front and the one from the left, behind. The posterior growth was not quite so large as the anterior, but more irregular in outline, and did not hang quite so low. It showed several large ulcerated areas, apparently the result of friction in walking, from which lymph continually exuded.

Owing to the location of the growths, a vaginal examination was not possible. There was no abnormality noted in any organ of the body. The patient, however, had lost about 20 pounds in weight since the appearance of the growths in December, 1912.

Examination of the urine was also omitted because it was impossible to secure a satisfactory specimen.

Blood examination revealed: white cells, 7,200; red cells, 3,400,000; differential count: polymorphonuclear neutrophils, 63.5; lymphocytosis, 17.3; large mononuclears, 15.4; eosinophils, 3.2; basophils, 0.6. The *Filaria sanguinis hominis* was not found. The Wassermann test was positive.

The specimen of tissue from the growths consisted of fibrous connective tissue showing an extreme condition of edema. There were small perivascular collections of round cells around the blood- and lymph-vessels.

View of growth from the rear, patient stooping.

Diagnosis.—When the case was first brought to my attention I felt confident that it was one of elephantiasis, and it might be well to review briefly this condition. Of course, it is a disease of the tropics, although sporadic cases are seen in the southern portion of the United States. Dr. Kelly reports quite a few well-defined cases. It is caused by the animal parasite, *Filaria sanguinis hominis*, of which there are two varieties, the *Filaria sanguinis hominis diurna* and the *Filaria sanguinis hominis nocturna*. The diurnal variety is found in the superficial vessels only during the waking hours, and the nocturnal is found only when the patient is asleep. It was a source of confusion to know how this curious phenomenon could be explained, and the puzzle was finally solved when a man who had the nocturnal variety was accidentally killed in the daytime, and the blood from his deeper vessels was examined, and was found to be swarming with filariae where they had gone in hiding until the

* Read before the Richmond Academy of Medicine and Surgery.

patient slept, when they would migrate to the superficial vessels where they were easily found.

In this condition the lymph-vessels are greatly dilated because of the blocking or choking of these channels, forming a varix, usually around the base or pedicle, together with large blood-spaces or sinuses, affording an excess amount of pabulum to the structures supplied, which accounts for the rapid growth of connective tissue. Accompanying this lymphedema, wherever there is a break in the continuity of the surface, there is usually a profuse lymphorrhea.

There is a condition caused by syphilis known as syphilis infiltrous in which the pathologic findings are identical with the foregoing, but in which the filaria is absent, and after numerous consultations I concluded this to be the correct diagnosis in this case.

Treatment.—Having arrived at this diagnosis, I determined to remove these growths and this was done by making an incision through the skin on the outer side of each growth the shape of the letter Y inverted so that the flap to be left had the appearance of an inverted V. This was done to allow for the retraction incident to the weight. Large venous blood-spaces were encountered with every stroke of the knife. They were easily controlled with clamps and many did not require ligatures. Care was taken not to injure the vaginal pouch, which I found pulled down and almost obliterated, but which retracted to a certain extent as soon as the growths were removed. A very satisfactory approximation of the skin-flaps was secured, rubber drainage-tubes were left *in situ*, and the usual dressings applied. In order that we might watch the immediate result of the operation, salvarsan was not given for one week, at the end of which time there was a general lymphedema and a profuse lymphorrhea with every indication of a rapid return of the condition. One week after the administration of salvarsan a marked improvement was noted, and in three weeks after the operation, a second dose was given. This was followed by a prompt disappearance of the edema, and the patient was soon able to be about her duties. The combined weight of the growths was 12 pounds. The patient passed from my observation in May when she left the city jail to serve a sentence in the state penitentiary.

Recently I was given an opportunity to secure a photograph which shows the patient to be in a very satisfactory condition. The labia are absent and only a small portion of the clitoris is left. The vagina is normal, and the patient has no leukorrhea or discomfort of any kind. Her general condition is excellent.

701 Grace Street West.

Traumatic Neuroses.—A. Ciampolini, the medical inspector for the state railroad system of Italy, has recently published in *Ramazzini*, 1914, viii, 1-108, an analytic study of 160 out of a total of 200 cases of neurosis following railroad accidents. The majority were commercial travelers and postal clerks; they seem to acquire what might be called a professional dread of accidents, and this is an important factor in the neurosis. The susceptibility to suggestion is extreme and a physician's incautious remark may start or aggravate the neurosis. The jar of the trains does not seem to predispose the trainmen to nervous trouble, as these formed only 12 per cent. of the total. Only 0.465 per thousand developed neuroses among 25,793 employees who met accidents of various kinds in 1909; and the proportion has been the same since. Ciampolini states that after the question of indemnity had been settled the neurosis gradually subsided with final complete recovery.

INFECTION OF NASAL CAVITY FROM DISEASED TOOTH-ROOT

SPECIMEN SHOWING PATHWAY OF INFECTION THROUGH THE MAXILLARY SINUS*

WILLIAM REDFIELD BUTT, M.D.

PHILADELPHIA

The possibility of the passage of an infection upward from a decayed tooth-root through the maxillary sinus to the nasal cavity is a matter of common medical knowledge. The rhinologist frequently finds in this sequence of events a long-delayed explanation, especially of trifacial neuralgias as well as various nose and throat conditions.

The accompanying illustrations are from a post-mortem specimen in which the pathway of such an infection is strikingly marked out by pathologic changes, namely, a necrotic area around the root of a first (or

Fig. 1.—Specimen showing: A, ethmoidal sinuses opened from orbital aspect and found to be free from any evidence of disease; B, polypi (upper one located at the lip of the ostium); C, area of necrosis around tooth-root; D, fistula from tooth-root opening on the gum; E, diseased first bicuspid; F, bristle passed from the maxillary sinus into the nose through the normal ostium.

Fig. 2.—Specimen showing: A, polyp in middle fossa of the nose growing from the lip of the unciform groove; B, bristle passing through the maxillary ostium beneath the middle turbinate.

second) bicuspid tooth, a fistula from this area opening on the gum, changes in the mucous membrane of the maxillary sinus adjoining this area and with polyp formation especially around the ostium, both on the maxillary sinus side and in the nasal cavity.

* Exhibited before the Section on Oto-Laryngology of the Philadelphia College of Physicians, and the Philadelphia Pathological Society.

The ethmoidal sinuses, opened from the orbital aspect, are seen to be uninvolved.

A point of interest in Figure 2, which, however, has no relation to the foregoing, is this: The sphenoid sinus in this case is represented by a very small depression on the back wall of the nasal cavity (hidden in the illustration) while the space below the sella turcica, usually occupied by the sphenoid sinus, consists of a thick mass of cancellated bone. The cavity shown in this region is not the sphenoid sinus, but was made artificially with the curet in searching for it. It is comforting to the surgeon working in this region to know that when the sphenoidal sinus is absent its territory is usually occupied, as shown in Figure 2, by a thick mass of bone.

CEREBROSPINAL EXAMINATIONS IN "CURED" SYPHILIS

CASES IN WHICH THE BIOLOGIC METHOD AS A CONTROL
HAS BEEN USED *

B. C. CORBUS, M.D.

Instructor in Genito-Urinary Diseases, Rush Medical College
CHICAGO

Since the application of the Wassermann reaction to the blood-serum as a biologic control in the treatment of syphilis, we have rested securely in the thought that this method of management, if applied correctly, was the last word in the prognosis of this disease. All authorities have recommended it as the most dependable aid which we have in the control of our treated cases of syphilis, and truly it is; but as discovery after discovery has followed in quick succession, each marking an epoch in our knowledge of syphilis, it is but natural that our opinions should change.

Noguchi's¹ demonstration of the *Spirochaeta pallida* in the brains of paretics has opened up a new phase of the infection, and whereas we before thought that this localization was only the end-result of the infection, we now know differently. That the spirochetes involve the central nervous system early, in a large percentage of cases, was little dreamed of three years ago, and only within the last year and a half has the management of this class of infections been given serious thought by the average syphilographer.

Since the application of lumbar puncture with spinal fluid examinations, many cases showing a negative blood-serum Wassermann for from eighteen months to two years without treatment show subarachnoid involvement. In the light of our present knowledge, lumbar puncture with spinal fluid examinations is demanded in all cases of syphilis, no matter at what stage of the disease, as a control on future complications of the nervous system.

An apology is offered for referring to the diagnosis of syphilis at the time of the presence of the primary lesion, as every syphilographer knows exactly the value of an early diagnosis, especially before the Wassermann is positive; but ever since the arrival of the easy water-soluble neosalvarsan, the treatment of this dis-

ease has passed out of the hands of the specialist into the hands of everybody with a medical degree. It is safe to prophesy that our insane hospitals in the future will contain a larger percentage of cases with involvement of the central nervous system than they do to-day. Too little heed is paid to this golden opportunity, and too great a dependency is placed on a few ill-timed "shots" with no consideration whatever of the subarachnoid space.

Since October, 1913, I have performed lumbar puncture with spinal fluid examinations on as many patients "biologically cured" as I could induce to return for examination. Of these so-called "cured cases," excluding syphilis with cerebrospinal manifestations, I have found spinal fluid involvement in 18.3 per cent. Many patients resting securely in the faith of a persisting negative Wassermann and good health refused to permit this procedure.

DISCUSSION OF THE TABLE

The accompanying table shows 6 cases of primary syphilis, 18 of secondary syphilis, 4 of tertiary syphilis, 14 of latent syphilis, 1 of congenital syphilis, and 6 of syphilis with cerebrospinal manifestations; of the last 6 cases, 2 are of incipient tabes, 1 of tabes, 2 of cerebrospinal syphilis and 1 of complete optic atrophy.

The original object of this investigation was to ascertain whether or not the "cure" had been complete, and if not, the reason.

Mott² long ago called attention to two factors which play a rôle in the involvement of the nervous system: (a) the specific form of spirochete, and (b) poor resistance on the part of the host. Having studied these cases with this idea in mind, I have deduced the conclusions which are given below.

PRIMARY SYPHILIS

All the cases herein recorded went to a satisfactory termination, and I believe are permanently cured. The largest quantity of salvarsan given to a single patient, together with rubbings, was 4.2 gm.; the smallest was 2.4 gm.

SECONDARY SYPHILIS

In Case 8 the patient, D. H. D., of average nutrition, had been infected nine years, and spirochetes were demonstrated in the mouth lesions before treatment was begun. On account of the length of infection before treatment, the patient being a confirmed alcoholic, subarachnoid involvement might be suspected. Examination was negative.

In Case 9 the patient, H. R. A., aged 38, was strong and robust, and spirochetes were present after five years. Jan. 27, 1914, spinal fluid examination was positive. After intensive intravenous salvarsan, spinal fluid examination April 29, 1914, showed Wassermann negative, cells 3 per cubic millimeter, Nonne negative. The total quantity of salvarsan given was 4.5 gm.

Patient 10, G. K. L., aged 51, was very well preserved. There was cerebrospinal involvement at eighteen months. This patient has had fourteen injections of salvarsan intravenously, being a total of 7 gm., together with rubbings by a professional, and four injections intraspinally, one after the Swift and Ellis³ technic, 20 c.c. of serum being given, and three after the method of Ravaut,⁴ 4 mg. being given at each injection. The spinal fluid is still involved.

Patient 11, C. G., aged 28, strong and vigorous, came under observation during the secondary period. The blood Wassermann always vacillated; spinal fluid examination, December, 1913, was positive, Nonne positive, and lymphocytes 25 per cubic millimeter. Since severe persistent intra-

4. Ravaut: Ann. de méd., 1914, i, 49.

venous medication, spinal fluid examination, March 24, 1914, revealed Wassermann negative, Nonne positive, and lymphocytes 3 per centimeter. Total quantity of salvarsan injected was 8.55 gm.

Patient 13, E. G. M., aged 24, was in good physical condition after two years' treatment, including five injections of salvarsan and mercury rubbings, the latter by a professional rubber, and showed a positive Wassermann on the spinal fluid. Later this patient received five intravenous injections at intervals of a week, making a total 5 gm. salvarsan. Second spinal puncture was refused.

In cases 14 and 15 (man and wife), each was treated differently; both show negative spinal fluid examination.

Patient 19, E. M. M., aged 28, robust and vigorous, had severe ulceration in larynx after four years. Spinal fluid examination is negative; blood Wassermann is still positive.

Case 23, F. E., is a reinfect case of syphilis, treated in 1911 for first infection, plaques and secondaries and positive blood Wassermann at this time. Patient since had negative blood Wassermanns Feb. 8, 1912, Feb. 4, 1913, Dec. 30, 1913. Second infection, exposed Feb. 15, 1914, secondaries with sore throat, May 22. Wassermann on blood-serum, positive. Spinal fluid examination negative.

was 13 years of age. At this time he had large gummas over both shins. Spinal fluid examination was negative.

SYPHILITICS WITH CEREBROSPINAL MANIFESTATIONS

Case 47 (N. DeH.) has a negative Wassermann; there have been two slight attacks of paralysis. The patient shows marked involvement of spinal fluid, and has been treated by the Swift and Ellis technic and Ravaut method.

Patient 49 (Mrs. E. S.), whose husband died of paresis, has occasional headaches, but is otherwise well. Wassermann is negative; there is enormous spinal fluid involvement. The patient has been treated with the Swift and Ellis technic and the Ravaut method.

Since beginning lumbar puncture with spinal fluid examinations I have made over 100 examinations.

Among some other cases that I have examined, three cases of secondary infection show involvement of the subarachnoid space; in three cases of latent infection with scarcely any treatment at all, spinal fluid examination is negative.

Considering the relation between the positive and

Fig. 1.—Dropping-glass, having the advantage of keeping the salvarsan excluded from the air at all times.

Fig. 2. — Converted syringe receptacle.

Fig. 3.—Record syringe with cap attachment.

TERTIARY SYPHILIS

Case 26, M. H. O., average weight 105 pounds, is the only patient in this series who showed involvement, and she is the wife of H. O., Case 36 under latent syphilis. Both show positive Wassermann on the spinal fluid.

Case 27 (M. D. H.) strong and vigorous, with a gumma on neck, was infected sixteen years before any treatment was begun. Spinal fluid is negative. One would suspect positive here.

LATENT SYPHILIS

Cases 30, 31, 37 and 38 are all cases of neglected treatment, in which one would suspect positive spinal fluid tests. All are negative.

Case 40 (F. O. B.) after provocative salvarsan shows positive blood and spinal fluid Wassermann.

Case 41 (Mrs. E. A., wife of E. A.) shows marked involvement of spinal fluid. I was unable to obtain husband's spinal fluid, at this time, but he is extremely irritable and spinal fluid involvement is possible.

CONGENITAL SYPHILIS

One would certainly suspect infection in Case 43 (H. H.), as treatment was not begun systematically until the patient

negative spinal fluid examinations in the marital infections alone, one would be strongly suspicious of a specific spirochete. That poor resistance on the part of the host plays a rôle in all infections is an absolute certainty, but who is going to point out the "weak"? I am sure I am not able to in my little experience.

That all infections with the *Spirochaeta pallida* are not potentially in the subarachnoid space should be readily conceded. Flexner⁵ has compared infections of this space with those of anterior poliomyelitis and those of pneumococcic origin. He shows clearly the futility of systemic medication in the latter infections. While the same holds true, in a measure, with syphilis, we are dealing with an infection that is slower in its progress, and as a consequence, our method of attack need not be so heroic at first. It is a mistake to begin injecting, intraspinally at the onset, every case of early syphilis in which there is spinal fluid involvement without symptoms.

5. Flexner, Simon: The Local Specific Therapy of Infections, THE JOURNAL A. M. A., Nov. 22, 1913, p. 1873.

The recent experiments with vital stains,⁶ trypan red and blue, show that it is possible to find these substances in the subarachnoid space after intravenous medication, as well as intraspinal injections, only in the latter it is more diffused and intense. For this reason I have preferred to adopt at first an intensive intravenous form of treatment, when no particular clinical manifestations are demonstrated, withholding intraspinal injections for the more severe and stubborn cases.

TREATMENT

The two methods of treatment available are intensive intravenous injections and intraspinal medication. In intensive intravenous injections, the plan which I have adopted is to give, in the early cases, as suggested by Collins,⁷ from five to seven doses of 0.5 to 0.4 gm. weekly, and then to rest three or four weeks, at the end of which time a puncture is made. If this shows a negative reaction, the treatment is resumed every other week for the same period of time, later once a month for three months, and still later, every other month. If a negative spinal reaction is maintained for a year, all treatment is suspended, but spinal examinations are recommended every six months. That this method is efficient is shown by examination of the blood-serum for salvarsan. Frequently it has been demonstrated in the blood-serum by the Abelin⁸ test ten days after the last injection.

While the time is relatively short to draw definite conclusions in regard to the merit of injections of salvarsanized serum, in intraspinal medication, most physicians who are familiar with the method realize the great value that comes from this form of treatment.

In another paper read before the Illinois Medical Society at Decatur in May of this year, my experience in the treatment of tabes on the service of Dr. Julius Grinker at the Cook County Hospital is given. The technic is the same as that used by Swift and Ellis, only the quantity used was from 15 to 20 c.c. undiluted with saline solution. Often pooled homologous serums were used.

Realizing the necessity of obtaining an equally efficient, as well as more rapid and simple means of medication, I have adopted the method of Ravaut as recommended by Wile,⁹ for direct intraspinal injections of neosalvarsan.

I dissolve 0.15 grm. of neosalvarsan in 5 c.c. of water (a hypertonic solution) in the dropping-glass (Fig. 1). This has the advantage of having a glass stopper and lessens the exposure to air.

A spinal puncture is made and the fluid is collected into the converted syringe receptacle (Figs. 2 and 3) up to 5 c.c.; the mandrin is reinserted to stop the flow, the desired dose is dropped into the syringe, the piston is placed in position, the syringe is inverted, fluid shaken up, the mandrin is withdrawn, connection made and the fluid reinjected. In following out the method, I have followed the practice of giving salvarsan every fourteen days intravenously, to take care of any possible systemic infection that might be present.

9. Wile, Udo J.: The Techn. of the Intradural Injections of Neosalvarsan in Syphilis of the Nervous System, THE JOURNAL A. M. A., April 11, 1914, p. 1165.

CONCLUSIONS

1. Too little attention is still paid to the diagnosis of syphilis at the time of the presence of the primary lesion.
2. A great majority of physicians fail to realize the golden opportunity that an early diagnosis presents.
3. Control of the treatment by the biologic examination of the blood-serum must be supplemented by spinal fluid examinations.
4. Intensive intravenous injections should always be tried first, in early cases, before intraspinal injections are resorted to.
5. Based on clinical observation, there is a strong possibility of a specific spirochete for the nervous system.

ADDENDUM

Since making the foregoing report at the session of the American Medical Association at Atlantic City in June, four out of seven cases under treatment show the following: One case with cerebrospinal fluid involvement, without symptoms, after 2 mg. of neosalvarsan injected according to the Ravaut technic as described above, showed bladder paralysis which still persists after six weeks; one case of tabes shows marked incoordination with marked numbness and anesthesia of the lower extremities; another patient with tabes is unable to walk at all; numbness and anesthesia are markedly increased; a fourth case shows the same symptoms, but, under strychnin, 1/60 grain three times a day, the patient has improved somewhat.

In the last three cases, the dose given was always 0.004 mg. and no symptoms appeared until after the third injection, the injections being made at intervals of two weeks.

In view of this later experience, which is somewhat comparative, I believe that the Swift and Ellis technic is superior and should be adhered to. If the Ravaut method is to be used at all, the dose should be extremely small and should be dissolved in at least 15 c.c. of spinal fluid.

THE TREATMENT OF SYPHILIS OF THE NERVOUS SYSTEM*

JOHN A. FORDYCE, M.D.

Professor of Dermatology and Syphilology, Columbia University, College of Physicians and Surgeons

NEW YORK

While it was recognized soon after syphilis became pandemic that the nervous system played a part in the morbid process, it appears that Knorre was the first, in 1849, to call attention to the fact that paralysis might occur in constitutional syphilis soon after or synchronously with the earliest symptoms. He cited five cases in three of which paralysis occurred three months after infection. Since then numerous publications by neurologists and syphilologists have appeared giving clinical evidence of the early involvement of the nervous system. Nonne⁴ has observed cerebral syphilis developing four months after infection and

On account of lack of space this paper has been abbreviated for THE JOURNAL. It will appear in full in the Transactions of the Sections and in the author's reprints.

4. Nonne: Syphilis and the Nervous System, translated by Ball, 1913.

mentions a case occurring simultaneously with the roseola. Leudt reported brain lues in two old persons three months after the appearance of the initial lesion. Mott⁵ has observed meningitis even before the primary sore was healed, and he is sponsor for the statement that the most severe cases of brain and spinal syphilis occur within the first twelve months. Naunyn collected 209 cases from the literature, to which he added forty-five of his own. From his analyses he came to the conclusion that infection of the nervous system took place in the majority of instances during the first year, after which there was a decrease in frequency. Braus' statistics, made up of 100 cases in which a history was obtainable, showed that in nearly one-half the nervous system was involved within the first year. In Fournier's clinic twenty-six cases were shown to have developed within from three to six months after infection. Hutchinson's fifteen cases of spinal syphilis appeared from six months to three years after infection, while Savard found that out of seventy-seven cases of myelitis, twenty-six appeared from six to eight months after the chancre. These observations on the clinical side have been considerably augmented during the past few years by laboratory findings.

In 1903 Ravaut⁶ undertook a systematic examination of the spinal fluid in secondary syphilis and found abnormal changes in about 70 per cent. of the cases. At the same time he made note of an apparent parallelism between the type of cutaneous eruption and the findings in the spinal fluid, having been impressed by the more frequent occurrence of abnormalities with papular, pigmentary and psoriasiform lesions than with the roseola. Plaut⁷ also obtained a rather high percentage; namely, a definite pleocytosis in one-third of the cases and border-line results in another third, leaving only one-third negative. Nonne and Mantoux placed their positive findings at 40 per cent. From the examinations of Altmann and Dreyfus,⁸ chemocytologic changes were present in about 80 per cent. of patients in the secondary stage with remains of the initial lesion. Gennerich⁹ found positive findings in about 90 per cent. He is of the opinion that all early constitutional cases, that is, those in which the Wassermann has become positive, will after an injection of salvarsan or mercury develop an increase in lymphocytes and globulin. In other words, a provocative or Herxheimer reaction will be obtained in the fluid. This concurs with the studies of Ravaut, Levy-Bing, Duroex¹⁰ and Dogny. Altmann and Dreyfus made similar observations. One of their cases in the initial stage with a negative blood and spinal fluid showed, sixteen days after treatment with 1 gm. salvarsan, fifteen cells. Another with a negative blood and fluid sixteen days after 1.4 gm. salvarsan had a marked increase in pressure. Two months later, during which time an additional 1.5 gm. had been given, twelve cells were found. Another patient in the early secondary stage with normal fluid was given 0.4 gm. salvarsan. Seven weeks later the patient had facial and acoustic paralysis with 180 cells and a strongly positive Wassermann. This was a characteristic neurorecidive, a number of which cases were reported early in the salvarsan era, but are no longer met under our more intensive methods of treatment.

My own investigations up to the present time do not coincide with the high percentage of anomalies reported by other observers. In the absence of clinical symptoms pointing to involvement of the central nervous system in the early secondary stage, I have found abnormalities in the spinal fluid in less than 20 per cent. The headaches of the early secondary period are frequently unattended by changes, and appear to be due to a hypertension rather than a meningitis. In the later secondary and tertiary periods the cephalalgia is accompanied more usually by a lymphocytosis and other findings and is the precursor of cerebral accidents. I still have this subject under investigation and will report on it later. My view at this time, however, is that too much importance has been attached to trivial changes, as differences in pressure or slight increase in globulin, and that probably no larger percentage show marked anomalies than later develop definite nerve changes. That such cases may be the subject for years of a chronic meningitis without objective signs has been shown by the researches of Vincent,¹⁰ who was able to follow for a number of years patients with marked fluid changes and no clinical symptoms, who later developed severe organic changes in the central nervous system, some paresis. It therefore seems probable that cases of syphilis of the nervous system are recruited from those with a chronic meningitis or latent residua, for we know that the older the infection becomes the greater is the tendency to localization or tertiarism. Whether or not a new infection or dissemination of spirochetes can take place from an old focus we must submit for future enlightenment. In this connection may be mentioned the positive inoculation obtained by Uhlenhuth and Mulzer¹¹ in a rabbit with the blood of a woman with latent syphilis, who had been delivered shortly before of a syphilitic child. Her infection dated back four years.

Clinical observations have taught us that only a minority of syphilitic individuals develop obtrusive nervous symptoms. Even under the old and inadequate methods of treatment the percentage is not very high. This may be accounted for partly by less complete methods of diagnosis, as the majority of statistics were compiled before the application of the Wassermann reaction or the lumbar puncture. Hjelmman placed his figures of cerebral syphilis at from fifteen to twenty-five per thousand. Raumont found that of 3,400 cases, 290 suffered from syphilis of the nervous system. Fournier's investigations of 4,329 cases of tertiary syphilis elicited diverse nervous manifestations in 1,085, of which 416 showed involvement of the cerebrospinal axis with more or less diffuse lesions. Pick and Bandler followed the fate of 2,066 cases, in the Prague clinic between the years 1879 and 1899 and found that 4.25 per cent. had developed parasyphilis. Most valuable are the statistics of Mattauschek and Pilcz.¹² In an admirable and painstaking manner they investigated the course of the disease in 4,134 officers in the Austrian army who had been infected during the years 1880 to 1900, and found that 198 developed paresis and 113 tabes, not counting those who later became paretic. Of the total number of tabetics 11.93 per cent. developed paresis; 8.18 per cent. had optic atrophy, not including the cases of

taboparesis; 132 patients suffered from cerebrospinal lues, most frequently the endarteritic form, and eighty other cases showed various psychoses.

Dreyfus examined 104 patients with latent syphilis, none of whom had symptoms pointing to involvement of the central nervous system. He found 77 per cent. normal. Of the remaining 23 per cent., only 12 per cent. showed marked changes. Inferring that the majority of patients suffer from meningeal involvement at the beginning of the infection, we must also infer that in a large percentage, cure takes place in spite of lack of or insufficient treatment, for in the cases under discussion Dreyfus mentions that treatment had been only symptomatic and far from adequate according to our present notions.

This leads us to another angle of the problem, namely, the question of "lues nervosa." It has long been the belief of syphilologists and neurologists that in nerve syphilis we are dealing with a different form of the infection. This had its origin in the observation of conjugal and family groups of metasyphilis as well as in persons infected at a common source. The question has been whether the factors which determine the later development of nervous syphilis reside in the infecting agent or in the host. Nichols¹³ has recently expressed the opinion that such spirochetes possess a highly invasive power rather than a neurotropic action. His deduction rests on the results he obtained with a strain isolated from the nervous system. He found that they had a thicker form and a shorter incubation period, producing in rabbits hard lesions with necrotic centers and showing a tendency to generalize with lesions of the skin and eye, following local inoculation of the scrotum and testicle. Steiner's experiments with rabbits showed that in only a few cases the nervous system is involved, in some the lesions are in the brain, in others in the cord. Dörfflein's work with the spirochetes of relapsing fever is perhaps also pertinent in showing that species, geographically separated, possess different biologic properties which are not distinguishable morphologically.

I have many times noted the involvement of the nervous system coincidently in husband and wife, and have at present under observation a woman with cerebrospinal syphilis whose husband had a paraplegia, a man with paresis whose child had hydrocephalus and a couple with taboparesis. Fischer¹⁴ found among 500 paretics conjugal metasyphilis in 10.2 per cent. In Fischler's¹⁵ analysis, husband and wife had general paralysis 26 and tabes 31 times; the husband tabes and the wife paresis 4 times, vice versa 15 times; both cerebrospinal syphilis 4 times; husband tabes and wife cerebrospinal syphilis once, and husband paresis and wife cerebrospinal syphilis once. Of the hereditary cases he found that when one parent had paresis the child had paresis 12 times and tabes 5 times. When one parent had tabes the child had tabes 10 times and paresis 3 times. It has been noted that when the types of conjugal metasyphilis are dissimilar, the man more often suffers from paresis and the woman from tabes.

Experience has demonstrated that many luetic affections of the nervous system are amenable to the treatment ordinarily employed, that is, mercury by injection or inunctions or by a combination of mercury with potassium iodid internally. The lesions which are responsive to treatment of this kind are certain types

of endarteritis, localized gummas, periostitis involving the meninges and disseminated forms of meningitis. There are, however, some forms of gummas and chronic meningitis with severe headaches and endarteritis with symptoms, such as irritability, loss of memory, and inability to concentrate, which do not yield to the old treatment, as well as the types of syphilis formerly described under the names of parasyphilis or metasyphilis. The latter were so resistant to treatment that it had long led to the belief that they were only indirectly related to the infection—rather the result than the direct effect of the action of the organisms. The investigations of Noguchi and Moore demonstrating the presence of spirochetes in the lesions of paresis and tabes have, however, definitely placed these so-called parasyphilitic affections among the active lesions of syphilis.

In the treatment of syphilis of the nervous system the important points to emphasize are first, accurate diagnosis with serologic findings, second, necessity of prolonged treatment, third, the avoidance of too large initial doses until the susceptibility of the patient has been determined, and fourth, persistence in treatment in spite of absence of amelioration following the first few injections.

The criticism of the results of treatment of the nervous system by writers who have noted no improvement or an aggravation of symptoms depends on the superficial way in which it has been carried out. No judgment can be rendered until patients have been subjected to a sufficiently long treatment to influence permanently the pathologic changes in the cerebrospinal fluid. They must be kept under continuous observation for a period of years, and until the four phases of Nonne have become negative, no assurance can be given against relapses. In other words, since the infection of the nervous system is more difficult to reach, and hence more persistent, the treatment should be carefully controlled not only by clinical results but also by lumbar puncture. We cannot form any conception of the activity of the process from the symptoms alone. The latter sometimes are out of all proportion to the laboratory findings. There are at present under my care two patients in both of whom the only complaint was headache and a feeling of malaise. In the one a cell-count of 314 with double plus globulin and positive Wassermann to 0.2 cc. was found. In the other there was present a pleocytosis of 746 cells, a great excess of globulin and a positive reaction to 0.025 c.c.

It is not possible at present to give a characteristic serologic picture for cerebrospinal lues, tabes and paresis. Bearing in mind that there are transitional or border-land forms, it is necessary to supplement laboratory findings with careful and minute clinical examinations. To obtain a proper conception of the serologic findings in early tabes, repeated examination of the fluid should be made in all patients presenting symptoms pointing to involvement of the nervous system. Many cases of tabes give a previous history of oculomotor paralysis, facial palsy, headaches, somnolency, irregularity of the pupils or other evidence of meningitis of the base. In other cases in which the process is limited to the lower cord, these early symptoms are lacking. With the acquisition of further data we may be able from a group of symptoms and spinal fluid findings to foretell the subsequent development of tabes. Gummas or endarteritic changes in the nervous system frequently occur, but recovery takes place

15. Fischler: *Deutsch. Ztschr. f. Nervenheilk.*, 1905, xxviii.

without secondary tabes or paresis, while cases with meningitis of the base may be followed by either of these conditions. The closer these conditions are studied from a serologic and anatomic point of view, the less likelihood is there that they are due to a primary neuron degeneration. Nonne¹⁶ is of the opinion that they are the result of a meningitis and refers to the work of Schröder, Meyer and Oppenheim demonstrating inflammatory changes in the pia and connective tissue passing from it to the blood-vessels. Nageotte also found a true inflammation with lymphocytes and plasma-cell infiltration about the root-fibers, as well as inflammatory changes in the arteries and veins. Stargardt likewise demonstrated a true inflammation of the sheath and endoneurium of the optic nerve in cases of tabes and paresis. It is possible for the specific infection to be limited to the cerebrospinal fluid, the blood being entirely free from the infection. This is proved by the negative findings in the blood and the positive ones in the fluid. It has also been demonstrated that the interchange between the blood and the spinal fluid is so slight that drugs introduced by the blood-stream diffuse themselves very little if at all in the spinal fluid. This fact explains the resistance of certain types of syphilis to the ordinary methods of treatment. Why this is so in one case and not in another is difficult to explain, unless we assume a more pronounced endarteritis in one case than in another or greater permeability of the choroid plexus. No matter what the theoretical considerations are, practical results show that the cells and other abnormalities can be influenced by intravenous treatment, although this takes place more slowly than with the direct method. That the latter is not only local in its action is shown by the change of a positive to a negative reaction in the serum by the exhibition of this treatment only.

The intraspinal method has placed the treatment of syphilis on a more accurate and scientific basis. As first applied by Swift and Ellis,¹⁷ it consisted of injecting into the subarachnoid space salvarsanized serum, that is, the serum from a patient treated intravenously with the drug one hour before. Diluted with normal saline it is given in strengths varying from 40 to 100 per cent. This method has been modified by Dr. Hanson S. Ogilvie by incorporating salvarsan with human serum direct *in vitro*, and has the advantage of standardizing the dose. For the procedure his technic is as follows:

Fifty c.c. of blood are drawn into a centrifuge bottle and centrifuged twice. It is important to have the serum clear and free from fibrin and blood-cells. To obtain the requisite amount of the drug, old salvarsan is mixed in the usual way in the proportion of 0.1 gm. to 40 c.c. of fluid, care being taken not to over alkalinize; 0.4 c.c. of this solution is the equivalent of 1 mg., and is taken as the standard for measuring the dosage. For this purpose a 1 c.c. pipet graduated in hundredths should be employed. The desired amount of salvarsan is added to from 12 to 15 c.c. of the serum, shaken to and fro to mix thoroughly, and then placed in the incubator at 37 C. (98.6 F.) for one hour, after which it is inactivated for half an hour at 56 C. (132.8 F.). The latter is a most important step in the technic, as Swift and Ellis demonstrated that the spirocheticidal properties of the serum were markedly increased by heating.

In experimenting with trypanosomes, Stühmer¹⁸ found that the curative action of unheated salvarsanized serum lasted twenty-four hours, and its protective action forty-eight hours, while in the heated serum the curative action was still present at the end of three days and the protective action four days. In comparing the relative values of salvarsan and neosalvarsan, he found that whereas the former was still active after forty-eight hours and often seventy-two hours, neosalvarsan lost its parasitocidal powers after twenty-four hours.

Salvarsanized serum prepared according to the method of Ogilvie must be used fresh, that is, within three hours of the time that it is made up. Patients should be prepared for its administration as for the intravenous injection, with a laxative the night before and only a light meal two hours prior to the treatment.

A lumbar puncture is made and an amount of fluid equivalent to the amount introduced is withdrawn. While the needle is *in situ*, the barrel of a Luer syringe is connected by means of a piece of rubber tubing. Spinal fluid is allowed to fill this to expel the air and the serum is then permitted to flow in by gravity. After its administration the patient should lie flat without any pillows, the foot of the bed being elevated for several hours. He must be kept in bed for at least twenty-four hours, in some cases forty-eight or seventy-two hours. Failure to do this may result in unpleasant symptoms, as pain in the extremities, headache, anesthesia, and bladder and rectal paresis.

The proper dose is still in a stage of evolution and a note of warning must be sounded against employing too large amounts. From my experience during the last months I feel that the limits of safety lie within 0.5 mg. It is better to begin with a dose of 0.25 mg., repeating or gradually increasing according to the tolerance of the patient. The intervals should be two weeks or longer. In a number of patients, when larger doses were given and the intervals were only a week apart, unpleasant by-effects were noted. These may come on within a few hours or be delayed for six days and may persist several weeks. The symptoms consist of root-pains, numbness, bladder and rectal paresis in some, irritability of the bladder in others, and ataxia. The numbness in some cases involved the whole lower portion of the body, in others the gluteal region and the legs with areas of hyperesthesia on the inner thighs.

On the Continent, where neosalvarsan is employed intraspinally, Marinesco and Minea¹⁹ and Ravaut²⁰ have given as much as 12 mg. at a dose. These large doses were followed in a number of cases by severe reactions.

On account of the technical difficulties connected with subarachnoid injection it is well to inaugurate the treatment of nerve syphilis with a few mercurial injections and follow this up by a course of intravenous injections of salvarsan, beginning with a dose of not more than 0.25 or 0.3 gm. and repeating these injections at varying intervals of from one to two weeks. At the end of six or eight such injections lumbar puncture should be repeated; and if a marked effect has not been obtained either clinically or serologically, a course of intraspinal injections should be seriously considered, the number and intervals to be governed by the reaction produced. Should at any

time symptoms of irritation manifest themselves; the patient should rest until they entirely disappear.

In the types of disease in which the symptoms are urgent and an immediate effect is desired, there can be no objection to beginning the intraspinal treatment without the antecedent intravenous employment of the drug, but better results are obtained by combining the two routes of medication. It must be borne in mind that a definite plan of treatment has not yet been formulated but that we are in a state of developing a method which seems to offer far more hope of influencing these resistant forms of syphilis of the nervous system than any heretofore employed.

Cases of tabes which are rather acute in their development, and have a high pleocytosis and positive Wassermann are advantageously treated by the combined use of mercury with the method outlined. In those accompanied by marked degenerative changes mercury may hasten the process. It therefore must be employed only after a careful analysis of the symptoms and serologic findings. An indication for intraspinal treatment alone would seem to be present in those cases in which we have a negative Wassermann in the blood and a positive one in the cerebrospinal fluid.

As I believe the results obtained with neosalvarsan are inferior to those obtained with salvarsan, I have practically given up the use of the former. It has been shown by Stühmer that, owing to its quicker elimination, its action is much shorter than that of salvarsan. While in each the maximum effect is produced within the first twenty-four hours, it practically ceases on the second day in the case of neosalvarsan, whereas in the case of the old he still found active traces at the end of a week.

The following group of cases is submitted to show the effect of intravenous and of intraspinal medication. Many of the patients had been treated for long periods of time by mercury and potassium iodid without improvement, and while the results are not uniform in all cases, in a number the improvement in the clinical and serologic symptoms is so striking as to encourage us in the further development of the method.

CASE 1.—Tabes. Man, aged 40, married, salesman. Syphilis eight years ago.

Symptoms: For one year pains in the legs, girdle sensation and marked ataxia. Absent reflexes; Argyll Robertson pupils.

Cerebrospinal Fluid; March 11, 1913: Cells 70, globulin ++; Wassermann ++ to 0.4 c.c.; serum ++.

Treatment: From March to June, eight injections of neosalvarsan, totaling 5.7 gm., and weekly injections of salicylate of mercury. No benefit resulted and treatment was discontinued. From Sept. 5 to Oct. 11, 1913, four injections of salvarsan amounting to 1.6 gm. Condition showed no change. Nov. 21, 1913, he was given an intraspinal injection of a 40 per cent. exogenous salvarsanized serum fortified with 0.25 mg. salvarsan. The effect of this treatment was cessation of the girdle-pains. Subarachnoid injections were continued until the middle of April, when he received the eighth with 1 mg. of salvarsan.

Cerebrospinal Fluid; April 16, 1914: Cells 0, globulin —, Wassermann ++ to 0.4 c.c.; serum ±.

Clinically a most radical change had taken place. The patient's nutrition had improved, he had gained in weight and no longer suffered from pain. The improvement in his gait was marked and he was able to go about unassisted.

Cerebrospinal Fluid; May 29, 1914: Cells 0, globulin —, Wassermann ++ to 0.8 c.c.; serum ++.

Treatment: Two intraspinal injections of 3 mg. and 3.5 mg., respectively. The latter was followed by severe root-pains.

This case is a very striking illustration of the value of subdural treatment, as there was absolutely no

amelioration in the symptoms from the other forms of treatment but a steady progression. Attention is called to the benefit obtained from the small doses and the error made in the large increase.

Blood-serum examined June 10, 1914, —.

CASE 3.—Tabes. Man, aged 55, married. Syphilis, 1901. Symptoms of tabes since 1906.

Treatment: From 1906 to 1912 injections of mercury. From April to October, 1912, six injections of salvarsan.

Cerebrospinal Fluid; Oct. 19, 1912: Cells 87, globulin ++, Wassermann ++ to 0.6 c.c.

Treatment: Three injections of neosalvarsan during the next year.

Cerebrospinal Fluid; Oct. 28, 1913: Cells 97, globulin ++, Wassermann ++ to 0.2 c.c.

Treatment: Five injections of neosalvarsan; Feb. 9, 1914, 0.5 mg. and March 10, 1914, 0.75 mg. salvarsan intraspinally.

Cerebrospinal Fluid: Cells 7; globulin ++, Wassermann ++ to 0.1 c.c.

Clinically: Improvement after intraspinal treatment marked. The pains in the legs disappeared, the patient no longer suffered from insomnia which had troubled him for many months and in every way his condition improved. This case also emphasizes the necessity of systematic and energetic treatment, as shown by an intensification of the process revealed by puncture under an irregular treatment of only three injections of neosalvarsan during the year.

CASE 6.—Tabes. Man, aged 55, married, broker. Syphilis twenty-six years ago with mild secondary eruption.

Symptoms: For past ten years pains and unsteady gait. During past year double vision, paralysis of the right external rectus, slight facial paralysis and attacks of vertigo. Knee-jerks absent; Romberg; pupils small, fixed to light and irregular outline, atrophy of the right nerve.

Cerebrospinal Fluid: Cells 45, globulin ++, Wassermann ++ to 0.4 c.c., serum Wassermann weakly +.

Treatment: From Feb. 16 to March 26, 1914, weekly injections of salvarsan averaging 0.3 gm. Early in April the patient had several attacks of motor weakness in the legs accompanied by temporary loss of consciousness, visual disturbance and attacks of aphasia. These symptoms were probably due to endarteritis and change in blood-pressure: May 5 he was given an intraspinal injection of 1 mg. of salvarsan, which was followed by retention of urine and vomiting lasting several days. May 14, 1914, 1 mg., May 20, 1.5 mg., and June 10, 0.5 mg. salvarsan were given subdurally.

Cerebrospinal Fluid: Cells 8, globulin ++, Wassermann —.

Clinically, the aphasia and motor weakness of the right upper extremity have disappeared, he is free from pain and his ataxia has improved some.

CASE 7.—Tabes and optic atrophy. Man, aged 52, married. Syphilis twenty-eight years ago.

Symptoms: For past sixteen years pains in the legs. Several years ago diplopia. Knee-jerks absent; marked ataxic gait. Pupils small and immobile, optic nerves pale, the right more so. Vision, right, 18/200, left 18/20.

Cerebrospinal Fluid; March 31, 1913: Cells 150, globulin ++, Wassermann ++ to 0.8 c.c., + to 0.6 c.c.; serum —.

Treatment: April 9, 1913, 0.45 gm. neosalvarsan, April 16, 0.6 gm. neosalvarsan. Latter was followed by increase in pain, diminished secretion of urine, delirium, and tremor of the hands, continuing until the 21st. From May 13 until June 23, six injections of neosalvarsan, a total of 2.85 gm., without any reaction.

Cerebrospinal Fluid: June 26, 1913: Cells 15, globulin +, Wassermann ++ to 0.2 c.c.

Treatment: Sept. 22, Sept. 29, Oct. 6 and Oct. 18, 1913, 30 c.c. of from 40 to 80 per cent. salvarsanized serum intraspinally, after the method of Swift and Ellis.

Cerebrospinal Fluid: Cells 8, globulin —, Wassermann —.

A period of rest followed this treatment.

Cerebrospinal Fluid; May 13, 1914: Cells 5, globulin ++, Wassermann very weak + with 1.0 c.c.; blood-serum very weak +.

Clinically, the pains have all gone, the ataxia is unchanged and the sight has remained stationary during the past year.

CASE 8.—Tabes. Man, aged 32, single. Initial lesion four-teen years ago; no secondaries.

Symptoms: Four years ago slight numbness of the toes. Six months later loss of coordination and now the typical symptoms of tabes.

Cerebrospinal Fluid: Cells 34, globulin ++, Wassermann ++ to 0.2 c.c.; serum ++.

Treatment: From Feb. 12 to May 5, 1913, ten injections of neosalvarsan, 7.1 gm., sixteen injections of mercuric chlorid, from 1/3 to 1/2 grain, and twenty-five inunctions.

Result: Marked improvement. The patient was stronger and had regained confidence, his walk had improved markedly and he was able to return to his work.

Cerebrospinal Fluid; June 2, 1913: Cells, 7, globulin —, Wassermann, —; serum —.

From that time until he presented himself again in March, 1914, he had had no treatment.

Cerebrospinal fluid, negative; serum ±.

There had been no clinical relapse except slight pains in the legs. Under a provocative injection of 0.3 gm. salvarsan, his blood-serum became strongly positive. After two more injections he was again punctured.

Cerebrospinal Fluid: Cells 5, globulin ±, Wassermann ++ with 1 c.c.

This case illustrates several points: first, the possibility of influencing the serologic findings along with the clinical symptoms by intense and regular treatment; second, the necessity of keeping patients under observation after negative findings are obtained, and third, the value of provocative injections. Since the latter the patient has had five intravenous injections of salvarsan, averaging 0.4 gm. each. He no longer suffers from pain, the bladder and bowels are normal, sexual power has steadily improved during the past year and there is scarcely any perceptible ataxia in his walk. When he first came under treatment his ataxia was so pronounced that he could not get about without assistance. He now walks daily from 5 to 7 miles, registered by a pedometer.

CASE 9.—Optic atrophy. Woman, aged 48, married, housewife. No history of infection; husband infected six years ago.

Symptoms: Five years ago double vision and other ocular disturbances. When seen in October, 1912, the patient had optic atrophy. Vision of the right eye 20/50; left, fingers at 4 inches.

Cerebrospinal Fluid; Oct. 16, 1912: Cells 24, globulin +, Wassermann ++ with 1 c.c., + to 0.6 c.c.

Treatment: Fourteen injections of neosalvarsan, 9 gm., and seven injections of salvarsan, 2.5 gm., accompanied by injections and inunctions of mercury.

A very noticeable improvement had taken place in the physical condition of the patient. All the headaches had ceased; the vision in the right eye was 20/20 and in the left fingers at 2½ feet.

Cerebrospinal Fluid; July 17, 1913: Cell 1, globulin —, Wassermann ++ with 1 c.c., and + with 0.8 c.c.; serum ++.

The benefit which this patient derived from treatment greatly exceeded the hopes of those familiar with this class of cases. The condition has been stationary for a year, without treatment, but the positive reaction of the spinal fluid and of the blood show the necessity of further combating the disease to hold the ground gained.

CASE 14.—Tabes. Man, aged 31, married, salesman. Syphilis nine years ago with secondaries.

Symptoms: Three years ago blurred vision and dilatation of left pupil. Now Argyll Robertson pupils; gastric crises; absent reflexes; slightly ataxic gait. Serum ++.

Treatment: In February, 1911, three injections of salvarsan, each 0.35 gm., followed by mercury.

Cerebrospinal Fluid; Oct. 10, 1912: Cells 43, globulin ++, Wassermann ++ to 0.4; blood-serum ±.

Treatment: Eight injections of neosalvarsan, 5.25 gm., along with mercurial treatment.

Clinically, the first two treatments were followed by a temporary improvement, but after several months there was a return of leg-pains, insomnia, loss of sexual power, weakness, etc. After the second course a definite change took place. The patient has gained in weight, the gastric crises and pains have ceased and his gait is normal.

CASE 15.—Taboparesis. Man, aged 38, married, manufacturer. Syphilis December, 1903, followed by secondaries. A marked cutaneous relapse in August, 1904; persistent eruption of the palms in 1905.

Symptoms: When seen in November, 1911, he had suffered from delusions of grandeur for two weeks. Eye-reflexes sluggish; knee-jerks absent.

Treatment: From Nov. 11, 1911, to Oct. 7, 1912, eleven injections of salvarsan, 4.2 gm., and seven injections of neosalvarsan, 4 gm., with mercury in the form of inunctions and injections.

Cerebrospinal Fluid; Oct. 10, 1912: Cells 86, globulin ++, Wassermann ++ to 0.2; serum ++.

Physical Examination. No sensory changes, station and gait normal. No paresthesia, no bladder or rectal trouble; both pupils very sluggish to light and accommodation. Mental examination negative except for a few obsessions with slight tendency to depression. No speech or writing defect.

Treatment: Injections of mercury to Jan. 31, 1913, and then discontinued.

Relapse: March 3, 1913 there was an epileptiform convulsion, and the patient was unconscious for twenty minutes. Nervous and excitable.

Treatment: Seven injections neosalvarsan, 4.65 gm., two salvarsan, 0.9 gm.

Relapse: In June, 1913, the patient became disoriented. Delusions and hallucinations both visual and auditory were very marked. He was extremely noisy and at times violent so that it was necessary to place him in a sanatorium and keep him under the influence of sedatives.

Treatment: July 16, 1913, an intraspinal injection of 30 c.c. of a 40 per cent. solution of salvarsanized serum after the method of Swift and Ellis; July 26, second injection; he became quieter and more tractable; August 4, third injection; distinct improvement the following week. He took his food and slept better, and grandiose ideas were less marked, but delusions of persecution persisted. August 14, fourth injection. After thirty minutes a mild convulsion. August 22, fifth injection. Steady improvement and only a tendency to be aggressive toward attendants and physicians. August 29, sixth injection. September 4, an intravenous injection of 0.45 gm. and on the following day an intraspinal injection. During the succeeding week a definite improvement in every way. He was brighter, had an insight into his condition, grandiose ideas practically disappeared and he was permitted to return to his home. Five more intravenous and five intraspinal injections were given.

Cerebrospinal Fluid; Oct. 21, 1913: Cells 6, globulin +, Wassermann ++ to 0.2 c.c. The first of the year he returned to business and during the month of February had one intravenous and one intraspinal treatment of salvarsanized serum.

Relapse: The latter part of March his brother died suddenly. This was followed by marked depression, insomnia and loss of weight.

Treatment: April 4, 1914, 0.75 mg. salvarsan subdurally; April 9, 0.4 gm. intravenously. April 23 the patient had a convulsion. April 25, 1.5 mg. intraspinally.

Cerebrospinal Fluid; April 25, 1914: Cells 15, globulin ++, Wassermann ++ to 0.05 c.c.

Treatment: May 12, 2 mg., May 22, 3 mg. intraspinally. The latter was followed by vesical incontinence persisting for several days.

Cerebrospinal Fluid: Cells 4, globulin ++, Wassermann ++ to 0.05 c.c.

Summary: Patient has received twenty-one injections of salvarsan, totaling 8.65 gm. fifteen of neosalvarsan, 9.25 gm.,

thirteen intraspinal injections of salvarsanized serum varying in strength from 40 to 100 per cent. (Swift-Ellis method), and five intraspinal injections in dosage from 0.75 to 3 mg. salvarsan, besides several courses of mercury by injection and inunction. At present he is normal again excepting for slight mental indecision.

CASE 18.—Cerebrospinal syphilis. Man, aged 29, single, clerk. Syphilis five years ago with secondaries.

Symptoms: Pupils sluggish, knee-jerks hyperactive, impotence for last two years.

Cerebrospinal Fluid; Feb. 2, 1913: Cells 46, globulin ++, Wassermann ++ to 0.6 c.c., $\pm$ to 0.4; serum —.

Treatment: Six injections neosalvarsan, 4.5 gm., six injections of salvarsan, 3 gm., and 100 grains of mercury salicylate from March 1 to June 1, 1913. This was followed by a period of rest to Nov. 4, 1913.

Cerebrospinal Fluid; Nov. 4, 1913: Cells 0, globulin —, Wassermann —.

This case shows the importance of lumbar puncture for the blood was repeatedly negative and remained so under provocative treatment, as well as the effects of a concentrated therapeutic attack.

Clinically, the symptoms gradually improved.

CASE 20.—Cerebrospinal syphilis. Man. A patient in the City Hospital. Syphilis three and one-half years ago.

Symptoms: For three weeks headaches and leg weakness; pupils fixed to light and accommodation. Patient also has multiple gummas of right leg.

Cerebrospinal Fluid: Cells 746, a very marked excess of globulin, the fluid coagulating almost solid, and a positive Wassermann to 0.05 c.c.

Treatment: Salvarsan, 1.5 mg. intraspinally; one week later the cell-count was down to 174 with a reduction in the globulin but no change in the Wassermann. The headaches were absent and the weakness in the legs had improved. After an injection of 3 mg. salvarsan intraspinally the cells dropped to 70, but the Wassermann was not influenced. The patient is now being systematically treated.

CASE 22.—Cerebrospinal lues. Man, aged 58, married, manufacturer. Syphilis thirty-five years ago. Deafness twenty years ago.

Symptoms: Fifteen months ago pains in lower extremities and ataxic gait; about a year ago partial paralysis of the left arm and leg and left side of face. This was followed two months later by a second hemiplegic attack with an epileptiform convulsion; patient unconscious for two hours. Pupils irregular and sluggish, knee-jerks absent, marked Romberg, pains and bladder weakness.

Treatment: Oct. 11, 1911, 0.2 gm. salvarsan and Nov. 3, 1911, 0.35 gm. salvarsan. These were both followed by an aggravation of symptoms, namely, the pains and twitching in the legs and vesical insufficiency. Two weeks later there was a remission in these symptoms and gradual improvement. Jan. 1, 1912, 0.3 gm. salvarsan, which was not followed by any reaction except loss of control of bladder during the night following the injection. During the next few months there was a gradual improvement in every way.

Cerebrospinal Fluid; Oct. 6, 1912: Cells 18, globulin ++, Wassermann ++ to 0.8 c.c.; blood-serum —.

Treatment: Six injections of neosalvarsan, 2.5 gm., were given. When seen in January, 1914, the patient had had no treatment for a year, the pupillary reflexes had become more active and the bladder function normal. His gait improved as well as his coordination. He is able to ride horseback and walk miles without fatigue. His blood-serum was —. It was not possible to do another puncture at this time.

CASE 23.—Endarteritis. Man, aged 49, married, manufacturer. Syphilis twenty-two years ago.

Symptoms: A year and a half ago the patient developed an attack of "pounding" in the ears followed instantly by sharp, severe pains in the head and unconsciousness for twenty-four hours. His vision remained blurred for many weeks and he had difficulty in articulating. He was very weak but had no definite palsies.

Treatment: Seven injections of neosalvarsan and mercury. Steady improvement took place.

Cerebrospinal Fluid; Feb. 20, 1913: Cells 6, globulin —, Wassermann ++ to 0.6 c.c., blood-serum ++.

Treatment: From Feb. 24 to March 22, 1913, he had five more injections of neosalvarsan, totaling 3.6 gm.

Clinically, no headache, no dizziness and patient feels normal.

In estimating the results obtained by the intensive treatment of syphilis of the nervous system one must not forget the influence of the psychologic effect of a new method of treatment and the fact that in many cases of tabes and paresis there are periods of remission covering months or years. Observations of this kind, however, were made before we employed the more precise methods of diagnosis and controlled our treatment by means of the examination of the spinal fluid. Furthermore, many of our most striking results have been obtained in patients who had long-continued and marked symptoms such as girdle sensation, pains and impairment of locomotion. The change in the clinical symptoms as well as the serologic findings would certainly give us strong presumptive evidence that the results were due to an actual improvement in the condition and not a normal remission.

Each case is a problem in itself and must be approached in an individual manner. Different pathologic conditions are present, so that while on the one hand we have an active process, on the other there is a degenerative one, complicated perhaps with an endarteritis, softening or scar formation. Symptoms which are due to interference with nutrition or pressure we cannot expect to influence.

When salvarsan is employed it should be done so intensively and combined with mercury. The criticism of certain writers against the employment of salvarsan in the secondary stage of syphilis is entirely fallacious, for we know that when it is given in the proper manner combined with mercury, the so-called neurorecidives do not occur. In an experience of over two years, during which this method of treatment has been followed, not a single case of nerve recurrence has been observed.

The cases submitted show that it is possible in some instances by intravenous medication alone to influence the clinical and serologic findings, and when this does not take place the only alternative may be intraspinal medication. Until we are more familiar with the effects of serum fortified *in vitro*, the Swift and Ellis method of salvarsanizing serum *in vivo* should be the one of choice. In certain cases the serum from a patient so treated may be reinforced with from 0.25 to 0.5 mg. of salvarsan. It must always be borne in mind that the spinal cord reacts intensively to irritants even of a mild grade. When a degenerative process is present the resistance of the cord is much below that of a normal one and the brunt of the irritation falls on the degenerated areas.

I am convinced that the intelligent and energetic treatment of the infection in the early stages properly controlled by the serum reaction would do much to prevent the subsequent development of nerve syphilis. It must, however, be thorough to eliminate the possibility of residual foci, which experience has taught have a predilection for the meninges. The early history of salvarsan shows that these accidents occur more precipitately after its use than under the older and milder methods of treatment.

8 West Seventy-Seventh Street.

THE SERO-ENZYME TEST FOR SYPHILIS *

F. W. BAESLACK, M.D., M.A.

DETROIT

Through the parenteral incorporation of foreign or changed protein into the organism we may observe the formation of enzymes in the blood of the body. These enzymes do not occur in the blood normally, but their presence is contingent on the entrance of blood-foreign substances. Conversely we are able to prove the occurrence of these enzymes in the blood by dialyzing such serum against the protein which gave rise to the enzymes.

The formation of these enzymes may be stimulated in the experiment at the will of the investigator, or it may take place in diseases of infectious origin, when the organisms themselves or the products of their action on the cells of the body, or both, are swept into the blood-stream and there cause the development of ferments which are capable of breaking up the complex foreign substances into their simpler non-specific component parts, which are either assimilated or thrown off. In this respect the normal and abnormal functions of the body differ quantitatively—for while, under normal conditions, the cells of the body split the complex specific molecules into simpler non-specific parts, there is added, under certain conditions, either physiologic or pathologic, the action of the ferments present or increased in the blood-serum which have the same function, namely, to split specific bodies into their non-specific components.

The work of Abderhalden has called attention to the formation and action of these ferments in pregnancy, in the course of which either chorionic epithelium or the products of the active metabolism as occurring in the syncytium may find their way into the blood-stream. Later Abderhalden extended his investigations to the diagnosis of neoplasms.

The controversy concerning the applicability of the dialyzing method for diagnostic purposes has found a fertile field in the sero-enzyme reaction for cancer, and a large number of observations have been made, which speak against the reliability of this method of diagnosis in this disease as far as it has been possible to determine, the failures may be due to a variety of causes, aside from possible errors in technic.

It is practically impossible to obtain cancer-tissue free from the connective-tissue stroma. The reaction for connective tissue is the same. This may be the reason why certain serums give positive reactions in other conditions than those clinically apparent. As the cancer invades an organ, there is usually degeneration of the neighboring tissue-cells and a consequent occurrence of protective enzymes in the serum of the patient against this cell protein. In addition, the cancer-cell may retain traces of the functional activity of the tissue from which it originated. Finally, the occurrence of protective enzymes in the serum is dependent on the breaking up of tissue in the blood and on the resorption of such broken-down tissue. Thus, an actively growing neoplasm may not give off cancer protein at all or may give it in such small quantities that the enzymes directed against it are not demonstrable. For these reasons the choice of the sero-enzyme diagnosis for neoplasms may not

have been a happy one to bring the conflicting conclusions into any relation. The use of homologous cancer-tissue, that is, tissue from patients who had the new growth in the same relation as that of the suspected patient, may possibly shed some light on this line of work. At least these contradictory results are no reason for excluding this method of diagnosis from all clinical application.

The extraordinary significance of the work of Abderhalden from a clinical and purely scientific point of view should be a stimulus to further research to determine the factors which have given rise to these divergent results.

The infectious diseases offer a more promising field for this line of investigation, since, in the course of such diseases, the causative organisms find their way into the circulation and there give rise to the protective enzymes capable of digesting them. Aside from this, we have in syphilis a disease simulating many other conditions in which cell proliferation and destruction occur, so that the resorption of these broken-down foci by the blood will further stimulate the formation of enzymes against the protoplasm of the cells undergoing degeneration as the result of the presence of the *Spirochaeta pallida* in the body.

Two hundred serums, obtained mostly from patients of the outdoor clinics of St. Mary's Hospital, form the basis for this investigation. While work reported in a previous paper,¹ the majority of serums tested were obtained from known syphilitics, it has been my aim in this work to test serums of patients suffering from various complaints to determine the extent to which this reaction could be relied on as a diagnostic means.

The technic followed in the course of this work has been the same as was employed for the fifty-five cases already reported. The tissue employed was the same, namely, the "gummas" resulting from the inoculations of syphilitic tissue or blood into the testes of rabbits. These lesions become, in the course of a few transplantations from rabbit to rabbit, free from secondary infection. They are practically non-vascular and contain the *Spirochaeta pallida* in large numbers.

Tissues from syphilitic patients, such as condylomas, gummas, etc., are usually secondarily infected and very vascular, for which reasons they are not suitable as tissues for the sero-enzyme reaction. The testicular tissue which has undergone mucoid degeneration due to the presence of the *Spirochaeta pallida* is of special advantage in the sero-enzyme test in that we are making use of a highly specialized tissue, against which protective enzymes are not likely to be found in the serum of patients. Thus the sero-enzyme test becomes a specific biologic test for the diagnosis of this disease. While the Wassermann reaction is a valuable aid in the diagnosis of syphilis, the principles underlying this reaction are not yet understood after years of investigation and general use.

Table 1 gives the clinical diagnosis as well as the serologic findings of the two hundred cases.

Eighty-five, or 42.5 per cent. of the entire number of cases gave a history of specific infection. Table 2 gives the number of each case as well as the serologic findings.

* Read before the Section on Dermatology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

* The designation to the left indicates the findings with the Wassermann reaction; to the right the result of the sero-enzyme test.

Table 3 gives the arrangement of these eighty-five cases according to the serologic findings.

TABLE 3.—ARRANGEMENT OF 85 CASES WITH HISTORY OF SPECIFIC INFECTION ACCORDING TO THE SEROLOGIC FINDINGS*

No. of Cases	Percentage	Wassermann Reaction	Sero-Enzyme Test
62	72.94	+	+
5	5.88	+	+
7	8.23	—	—
8	9.41	—	±
1	1.16	±	±
2	2.32	—	±

* In this table + = positive; — negative; ± doubtful.

Out of the 5 cases which gave a positive Wassermann reaction and a negative sero-enzyme for syphilis, 3 were cerebrospinal fluid which does not contain enzymes—Cases 70, 114, 123. The 7 cases giving a negative Wassermann reaction and a positive sero-enzyme syphilis reaction were, 3 in the primary, 1 in the secondary, 1 in the tertiary and 2 in the latent stages of syphilis. Case 54, primary chancre, gave a doubtful Wassermann reaction and a positive sero-enzyme. Cases 13 and 172, also primary chancre, gave a negative Wassermann reaction and a doubtful sero-enzyme reaction for syphilis.

TABLE 4.—ARRANGEMENT ACCORDING TO SEROLOGIC FINDINGS OF 115 CASES IN WHICH THE SPECIFIC HISTORY WAS NEGATIVE

Number	Percentage	Wassermann Reaction	Sero-Enzyme for Syphilis
54	26.95	+	+
23	20.00	+	+
13	11.3	—	—
44	38.26	+	±
4	3.47	+	±

Out of the 115 cases giving no history of specific infection 24 presented clinical symptoms of the disease.

In summarizing the findings of Table 5 we find the Wassermann reaction positive and sero-enzyme reaction positive in 12 cases or 50 per cent.; Wassermann

reaction positive and sero-enzyme reaction negative in 3 cases or 12.5 per cent.; Wassermann reaction negative and sero-enzyme reaction positive in 8 cases or 33.33 per cent.; Wassermann reaction negative and sero-enzyme reaction negative in 1 case or 4.16 per cent.

TABLE 5.—CASES IN WHICH SPECIFIC INFECTION WAS DENIED, DIAGNOSED CLINICALLY AS SYPHILIS

1	Alopecia areata, gastric disturb.	58	+++	+

17	Secondary syphilis	73	++	+
18	Secondary syphilis	101	++	+
19	Secondary syphilis	197	—	+
20	Syphilitic ulcers on legs	38	—	+
21	Syphilitic ulcers on legs	60	+++	+
22	Syphilitic ulcers in nose and throat	165	+++	+
23	Syphilitic ulcers on right tonsil	194	—	+
24	Tabes	122	—	+

The 3 cases giving a positive Wassermann reaction and a negative sero-enzyme syphilis reaction include 2 cases, that is, Cases 4 and 12, in which spinal fluid was tested. The cerebrospinal fluid does not contain the protective enzymes. The 8 cases giving a negative Wassermann reaction and a positive sero-enzyme syphilis reaction were: 2 cases of primary syphilis (Cases 66 and 195), 1 secondary (Case 197), 2 latent (Cases 19 and 25), 2 had syphilitic ulcers (Cases 38 and 194), and 1 case of tabes (Case 122). Aside from the 12 cases found to be positive to the Wassermann reaction and sero-enzyme test for syphilis in the series clinically syphilitic, 19 others were found among the remaining 91 whose serums reacted positive in both tests, or 16.52 per cent.

TABLE 6.—WASSERMANN REACTION AND SERO-ENZYME TEST POSITIVE IN CASES IN WHICH SPECIFIC INFECTION WAS DENIED

	No.	Case
1	1	71
2	1	141
3	3	78, 196, 200

WASSERMANN REACTION POSITIVE, SERO-ENZYME DOUBTFUL

1	Blindness (total)	1	103
2	Coryza	1	76
3	Dizziness	1	111
4	Ulcerative condition of the toes	1	142
		4	

Of the 4 cases giving a positive Wassermann and a doubtful sero-enzyme reaction, Case 142 gave a single positive Wassermann while the remaining 3 gave double positive results. These latter 3 patients

may be suffering from specific infection although no clue to it could be elicited in their history.

The Wassermann reaction was positive and the sero-enzyme test for syphilis negative in 20 out of 115 cases, or 17.39 per cent. It is interesting to note that 9 cases of tuberculous condition, in Table 7 gave a positive Wassermann reaction which, though faint, was distinct. Tuberculosis is capable of giving a positive Wassermann reaction. If we subtract the 9 cases of tuberculosis in Table 7 and Case 161, cancer of the throat, we have left 10 cases which possibly might be syphilitic.

TABLE 7.—WASSERMANN REACTION POSITIVE, SERO-ENZYME TEST NEGATIVE

		Case	No.
1	Asthma	1	160

SUMMARY

1. In conclusion I would point out that in the sero-enzyme test for syphilis, when carried out with syphilitic testicular tissue, is probably a specific reaction, since the somatic cells are highly specialized, presupposing a specific enzyme for their cleavage. Thus, in the use of the gumma produced in rabbits by inoculation, we make use of a substratum which, when free from contamination, is superior to tissue prepared from the tissue of syphilitic patients, which of necessity is contaminated and is likely to give rise to positive reaction in other conditions.

2. The reaction is not applicable in cases in which cerebrospinal fluid is to be tested.

3. The reaction is more specific than the Wassermann reaction, for it has always given a positive reaction with the serum of tabetics, while the Wassermann reaction in this condition is negative in about 40 per cent. of cases. I would also point out the nine cases of tuberculosis which gave a positive Wassermann reaction although no sign of syphilis could be found in any of these patients. The specificity of the test is further shown in the 8 cases giving a negative Wassermann reaction and a positive sero-enzyme test (Summary of Table 5).

4. The technic of the reaction demands cleanliness and careful control of shells, tissue, serum and the carrying out of the ninhydrin reaction. As one becomes acquainted with the test one's confidence in it increases.

5. The sero-enzyme test for syphilis represents, with the exceptions indicated, a true biologic test for this disease.

THE INTRAVENOUS ADMINISTRATION OF
MERCURY IN SYPHILIS *

JEROME KINGSBURY, M.D.

AND

PAUL E. BECHET, M.D.

NEW YORK

This method was first used by Bacelli in 1893, and subsequently by Blaschko, Lewin, Chopping, Lane, Abadie, Campana, and Stoukownenkoff and others. The method in recent years has apparently fallen into disuse, very few articles on the subject being found in the literature. This may be due to the rather discouraging attitude of Fournier, who looked on the method with disfavor. He is under the impression that a toxic agent, such as mercury, suddenly placed in contact with the endometrium, may possibly exert a deleterious effect on it. His supposition is based on the experiments of Ullman. While Ullman has never seen an animal die after the intravenous injection of large doses of mercury, yet in a few cases in which death occurred later, there were no lesions which would account for the death of the animal, and Fournier reasons that death might have been caused by paralysis of the heart, engendered by the previous injections of mercury. Two comparatively recent articles on the intravenous injection of mercury in the treatment of syphilis are by Meyer, whose results were disappointing.

* Read before the Section on Dermatology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

and Lydston, whose results in eight cases were very gratifying. Wernick appears enthusiastic, after twelve years of experience with the intravenous injection of mercury. Balzer, at the French Medical Congress of 1904, endorsed it for cerebral and ocular syphilis. Ravant uses the cyanid of mercury, intravenously, as a preliminary to salvarsan therapy.

Our experience with this method is derived from its use at the New York Skin and Cancer Hospital, in a large number of cases of cutaneous syphilis. We first used the bichlorid in doses of $\frac{1}{6}$ to $\frac{1}{3}$ grain in distilled water. On an average, six injections were given in each case. Our best results were attained with this salt. We also used the benzoate in a 1 per cent. solution in normal saline, of which the dose was from 2 to 12 c.c. While the results with this salt were good, they were inferior to those obtained with the bichlorid. Enesol¹ in our hands proved very unsatisfactory, and a proprietary preparation of mercuric oxycyanid also gave inferior results.

The technic of the injection is simple, provided that the subject has prominent veins, otherwise the percentage of failure to get the needle in the lumen of the vein is in proportion to the experience of the operator in intravenous work. The most prominent vein at the bend of the elbow of either arm is selected, the region sterilized with alcohol, and a constricting band, preferably a piece of rubber tubing, applied to the lower third of the arm. The patient closes the fist tightly so as to increase the tension in the veins. The filled glass syringe with needle attached, is inserted in a vertical direction through the skin, and then directed obliquely into the vein. The direct flow of blood into the barrel of the syringe is sufficient indication that the needle is within the lumen of the vein. The constricting band is removed, and the mercurial solution with the admixed blood is slowly injected. The amount of solution used varies of course with the particular dose which we wish to give, but it rarely exceeds 12 c.c.

The advantages of the intravenous method are: immediate introduction of the curative agent in the circulating blood, rapid therapeutic results, mathematical dosage and absence of pain. The most important disadvantage is the occasional occurrence of phlebitis, and periphlebitis, which seemed more frequent after the use of the bichlorid than of the benzoate; this complication, however, occurred only in our early cases, when the solution used was more concentrated. A small number of the patients suffered from ptialism and a few others developed mercurial diarrhea, but, in none of the cases did these complications cause anything more than a temporary disturbance.

The results in our hands in cases where the rapid removal of lesions was desired were uniformly good. Among the cases we recall was one with an extensive palmar lesion of the right hand of ten years' duration; it entirely disappeared after two injections of 4 and 7 c.c., respectively, of a 0.5 per cent. solution of benzoate of mercury. Another case with two large serpiginous, greatly infiltrated, and crusted lesions, several inches in diameter, on the left hand and wrist, cleared up entirely after the third injection. Still another lesion involving half the palm of the left hand, which had resisted mixed treatment for four months, cleared up entirely after the third injection. A

gumma of the right thigh disappeared entirely after three injections. An extensive secondary eruption of the pustular type resolved after four injections, leaving scales of dried pus, which were easily removed, disclosing an entirely healed lesion beneath. An extensive raised, grouped, papular lesion of the left cheek was rapidly resolving, and had lost all of its infiltration; the lesions were even with the skin after three injections. An ulcerated, serpiginous lesion, 4 inches long by 1 inch broad, and greatly crusted, healed entirely after two injections.

These are a few of the many cases which impressed us with the rapid therapeutic results obtained with this method, and we are strongly convinced that despite its obvious disadvantages it is of great value in selected cases. It is not to be used indiscriminately, however, and we do not recommend it for routine administration.

ABSTRACT OF DISCUSSION

ON PAPERS OF MRS. WHITE, HAZEN, NICHOLS, BAESLACK, FORDYCE, CORBUS, AND KINGSBURY AND BECHET

DR. WILLIAM T. CORLETT, Cleveland: Dr. White emphasized the fact that patients themselves are often responsible for much of the misery and many of the late lesions that follow in the course of syphilis. His statistics show that in a large percentage of cases, patients come to the hospital for treatment for only a few days. In our experience at the Lakeside Hospital, in a large percentage of cases, patients were treated for only three days, a still larger percentage for two or three weeks, etc. This confirms the experience of Dr. White and shows that the patients themselves do not realize the importance of their disease or the value of thorough treatment from the beginning. We have endeavored to educate such patients by distributing a printed circular setting forth some of the possible dangers of the disease, if left untreated, and also emphasizing the precautions that they should take to guard against infecting others, and the probable length of time that it will be necessary to follow out a systematic course of treatment. Furthermore, even physicians are not alive to the importance of treatment during the primary stage of the infection. We have endeavored, especially, to give heroic treatment in appropriate cases at the outset of the disease, and while it is extremely difficult to speak with assurance on this point, we believe that in a few instances we were successful in curing the disease in this way, as a few patients have been kept under careful observation for at least two years without showing further manifestations of syphilis. I believe that 99 per cent. of the physicians in this country are incapable of treating the disease according to the advocated standard, and that the root of the trouble lies with the medical schools and hospitals. The haphazard way in which the delicate technic advocated by Dr. Fordyce and required in intraspinal treatment, is carried out in many hospitals where the work is often left to young inexperienced interns and without intelligent supervision, is appalling. In the light of this symposium more than ever do I believe that the hospital treatment and medical-school teaching of syphilis, in all its phases, should be under the guidance of one particular man with the cooperation of the other members of the staff.

DR. S. POLLITZER, New York: In a paper read before the New York County Medical Society in January, 1911, I developed the theory that the spirochetes soon after infection were distributed throughout the entire system, involving every organ and tissue reached by the blood-stream. There most of them were probably destroyed by the natural forces of resistance, but many doubtless passed over into a resting or spore stage in which they remained indefinitely without harm to their host till under some local stimulus, such as a trauma, they renewed their activity and produced the lesions of tertiary syphilis. This theory seems to me a necessary

1. See Enesol, an Arsenic and Mercury Preparation of Uncertain Composition, Propaganda Department, THE JOURNAL A. M. A., July 26, 1913, p. 292.

conclusion from the known facts of biology and the clinical course of syphilis. To obviate the late lesions of the disease every case should be treated at its very inception by the most intense medication at our command. The question of the best method of treating tabes and paresis is by no means settled. Treatment by intraspinal methods is still in an experimental stage and the present state of our knowledge of these methods does not justify their general adoption. The working out of the details should be left to those who are qualified by their larger opportunities to carry them out. The intraspinal methods give promise of usefulness; but we must realize that no possible treatment can restore nerve fibers and cells that have been destroyed. I employ the Ravaut method, direct injection of hypertonic solutions of neosalvarsan, and while I have had some very unpleasant immediate symptoms, I have had no permanently bad results from it. Meanwhile it is well to remember that these forms of syphilis are immensely benefited by energetic treatment by other methods. For the past two years I have had a patient with paresis under observation whom I took out of the psychopathic ward at Bellevue Hospital and gave sixteen injections of salvarsan, in all 10 gm., in sixty days. That man is to-day apparently well; his blood-Wassermann is negative, his spinal fluid contains three cells to the cubic millimeter, globulin negative, Wasserman negative with all but the maximum quantity of fluid. I shall report on the final outcome of this case in ten years. It is unfortunate that the treatment of syphilis in its early stage is almost exclusively in the hands of the general practitioner, who so often contents himself with prescribing some pills and loses sight of the patient with the disappearance of the first symptoms. It is unfortunate that he does not realize his opportunity and his responsibilities. There is reason to believe that, in its earliest stage, syphilis can be cured by excision of the chancre and a single energetic course of salvarsan and mercury. It is equally true that the specialists for the eye and throat treat their cases of syphilis badly, that is, symptomatically. They also stand in need of education on this subject.

DR. C. AUGUSTUS SIMPSON, Washington, D. C.: The percentage of syphilis among the negroes of Washington is very high, as they rarely persist in the prescribed treatment. I think that the number of cases among the white population is not so great as in some other sections of the country, and that the amount of syphilis among the white patients that visit Freedmen's Hospital of our city is no indication of the number of cases there, as very few white patients can be treated in a negro hospital and the class that does apply for treatment is, as a rule, the very class in which one would expect to find a large number of syphilitics. The frequency of syphilis of the nervous system in the future will depend a good deal on the thoroughness and conscientiousness with which the medical man carries out his treatment and blood-tests. If he cannot distinguish between a negative provocative Wassermann and a negative plain Wassermann he will soon get into trouble. The latter means little or nothing so far as a cure is concerned. An effort should be made to get a negative luetin reaction, while a negative provocative test should be insisted on before the patient is allowed to stop his treatment.

DR. A. RAVOGLI, Cincinnati: The syphilitic patient usually gets what he deserves. Patients who refuse to undergo proper treatment for the prescribed length of time and who drink alcoholics and neglect themselves are very apt to suffer in the future. There is no doubt that syphilis is very common among the negroes, and in my hospital work it is exceptional to find an adult negro who is free from the disease or does not give a history of a past infection, while among the negro children, evidences of hereditary syphilis are very frequently observed. In the colored race, syphilis is probably more severe than in the white, and this I am rather inclined to attribute to the nonchalance with which the former usually regards his infection. He looks on the disease with apparent unconcern, and usually cannot be restrained in the hospital for more than a few days. There

is no question that we have obtained very good results in the mercurial treatment of syphilis in the past. Some time ago I was asked by a French writer how many of my syphilitic patients had developed tabes or general paresis, and on reviewing my books, I found very few. In many of my cases, intramuscular injections of a 1 per cent. solution of mercuric chlorid, and later, gray (mercurial) oil and calomel, gave very satisfactory results, and now, of course, in salvarsan, we have another powerful weapon. The use of intravenous injections of mercuric oxycyanid, as recommended by my teacher, Professor Baccelli, and used by Ernest Lane of London, apparently gave no better results than those I have obtained by the older methods of intramuscular injections and I think the intramuscular injections are preferable to the intravenous. This does not apply, however, to salvarsan, which gives its best results when injected into the veins, and does not produce so severe pains as it does when injected into the muscular masses. I have never used the intradural injections, and I was much interested in the results obtained by this method.

DR. THOMAS W. MURRELL, Richmond, Va.: Every southern man feels a vital interest in syphilis in the negro which is more important to him than leprosy, and this condition has been practically forced on the negro by the national government. Before the Civil War, the negro was a commercial problem. His physical as well as his moral condition was well looked after, as is shown by his conduct up to that time. Then he was turned loose, his naturally strong sexual instincts were no longer held in control, he began to drink to excess, to eat poor food, to live in a hovel, to be insufficiently clothed, and gradually he went from bad to worse until now the death rate among the negro is higher than that of the white race, while the birth rate, in spite of the well known procreative power of the black race, has steadily grown smaller. Syphilis is very common among them and insanity in the State of Virginia has increased 1,000 per cent. since 1865. Its increase, in fact, is one of the problems of the state. In our dispensary work in Richmond we make the Wassermann test in negroes as a routine measure, and it is almost invariably positive. Of all the specimens of blood taken, probably 75 per cent. show a positive Wassermann. We can sometimes reason out things, even if we are not laboratory men, and I believe that some of us have a mistaken idea as to the relative value of salvarsan and mercury in syphilis. Salvarsan is a spirillicide, but I do not think the same can be said of mercury. In England, at one time, the accepted method of treatment was to give mercury to the point of salivation. We can keep a patient saturated with mercury, and yet we do not kill the spirochetes, and in any bacterial invasion of the body we have the formation of toxins which are produced either by the bacteria or by the body. In our efforts at treatment, we must destroy the organism, neutralize the toxins and strengthen the bodily resistance, and the action of mercury is to neutralize the syphilitic toxins and allow the bodily resistance to take care of the situation. One error that is too often made is to rely too much on drugs and leave the condition of the patient out of consideration.

DR. CLAUDE O. ABERNETHY, Raleigh, N. C.: I do not think that the intraspinal method of treating late syphilis should be generally adopted, at least in the present state of our knowledge, nor do I think it necessary. I have at present under my observation a case of progressive paralysis of the lower extremities in a patient with late syphilis who is rapidly improving under intravenous injections of salvarsan, combined with mercury and the iodids.

DR. H. H. HAZEN, Washington, D. C.: My paper was really intended as a provocative one, for we are not paying the proper attention to all of the aspects of syphilis. This malady is certainly not properly treated in the hospitals, the economic side of it has never been carefully studied, and the methods of prevention are very crude, to say the least. For instance, in my clinic we frequently see women with active secondary lesions, including mucous patches, attending to the babies of ignorant or foolish parents. This is not right

and we should have some authority to stop it. With regard to the relative frequency of syphilis among the whites and blacks, the statement that I made was that, in spite of the showing of certain localized statistics, general statistics showed that the negro suffered from syphilis one and one-half times as often as the white. At present we are having a good many Wassermanns made, but unfortunately have not as yet been able to adopt it as a routine measure. In the negro our statistics show about 30 per cent. positive, while at Johns Hopkins I understand nearly 50 per cent. in this race are positive. I am inclined to think that mercury is a spirillicide, because if one makes a dark-field examination of a lesion and finds a great number of organisms, then gives an intramuscular injection of gray oil, and again searches for the parasites, in twenty-four to forty-eight hours he will find a great reduction in their numbers.

DR. HENRY J. NICHOLS, Washington, D. C.: I see no reason why the spirochete should not remain in the body for many years as a spirochete, and the weight of evidence is rather against a spore stage. Still, there are several gaps in our knowledge of the subject and further experiments will be necessary to complete the chain of evidence.

DR. JOHN A. FORDYCE, New York: I wish to emphasize what I said with regard to the Ravaut method of intraspinal injections as compared with the Swift-Ellis method. It seems to me that the latter method is not so apt to be followed by any of the bad consequences of the Ravaut method.

D. B. C. CORBUS, Chicago: Since last fall, when I began to work along these lines, I have seen quite a number of patients with syphilis who were supposed to be cured and who gave a negative blood-Wassermann reaction, but who, on spinal puncture, showed subarachnoid involvement. I desire, therefore, again to call attention to the importance, especially in this class of cases, of an examination of the cerebrospinal fluid, the technic of which should be more generally understood and applied.

DR. PAUL E. BECHET, New York: Dr. Ravogli, in discussing the intravenous injection of mercury in syphilis, mentions pain as a prominent factor in patients treated by a confrère of his. The pain was undoubtedly caused by the invasion of the perivascular tissue, by the mercurial solution. If the needle is within the lumen of the vein, there is no leaking of the solution outside of it, and the operation is consequently absolutely painless.

THE ETIOLOGY OF PHLYCTENULAR OPHTHALMIA

IS TUBERCULOSIS REALLY AS IMPORTANT A FACTOR IN THE CAUSATION OF THIS DISEASE AS IS NOW COMMONLY TAUGHT? *

SAMUEL THEOBALD, M.D.

Clinical Professor of Ophthalmology, Johns Hopkins University Medical Department; Ophthalmic Surgeon to the Johns Hopkins Hospital and to the Baltimore Eye, Ear and Throat Charity Hospital

BALTIMORE

Few questions in ophthalmology have been more discussed in recent years than the etiology of phlyctenular ophthalmia. This is accounted for by the fact that during this period the theory has been advanced, and has been supported by many eminent ophthalmologists, that phlyctenulosis is a tuberculous manifestation.

The advocates of this doctrine unceremoniously reject the older view of the etiology of this affection, which led especially German writers on diseases of the eye to designate it as ophthalmia eczematosa, and, in conformity with their convictions, urgently com-

mend in its treatment the employment of tuberculin, as the most efficacious remedial agent at our command. This being the case, it is evident that the true nature and causation of phlyctenular ophthalmia is not merely an academic question, but is one of very practical importance; for, after all, if it is really not tuberculous, the use of tuberculin in its treatment is sure to do more harm than good, and is most distinctly contra-indicated.

Let us, then, consider the evidence which has been advanced in support of the new doctrine, and try, impartially if we can, to determine its import. And here it may be premised that the advocates of the tuberculous theory no longer contend that the conjunctival or corneal phlyctenules are examples of true ocular tuberculosis, since they are compelled to admit not only that they never contain tubercle bacilli, and that tuberculosis has never been produced in animals by inoculating them with the contents of the phlyctenules, but that histologically the phlyctenules bear no resemblance whatever to true tuberculous tissue. What they do maintain is that phlyctenulosis is a pseudotuberculous or paratuberculous affection, caused by the action of the toxins of tubercle bacilli present somewhere in the body.

In support of this belief they cite:

1. The frequency—from 70 to 90 per cent., according to different investigators—with which the subjects of phlyctenulosis give a positive reaction to diagnostic tests with tuberculin, the von Pirquet test being chiefly relied on.
2. The efficacy of tuberculin in the treatment of phlyctenulosis, and especially its efficacy in controlling chronic cases and those showing a tendency to recurrence.
3. The development of phlyctenular conjunctivitis and keratitis after the application of tuberculin to the eye, and after other diagnostic tuberculin tests.
4. The occasional occurrence in phlyctenular ophthalmia of focal reaction following diagnostic or therapeutic injections of tuberculin and after the von Pirquet test.
5. The chronicity and tendency to recurrence of the disease, its predilection for the poorly nourished and for those in whom the existence of the so-called strumous or scrofulous diathesis is manifest, and the glandular complications which frequently accompany it.

Before taking up this summary of the evidence advanced in support of the tuberculosis theory, let us, for a moment, consider the significance of the admitted non-existence of tubercle bacilli in the phlyctenules, and, further, the present assertion that phlyctenulosis is a pseudotuberculous affection, due to the toxins of the tubercle bacillus.

Dr. John W. H. Eyre,¹ Hunterian professor, and examiner in bacteriology, Royal College of Surgeons, in his Hunterian lecture on "Tuberculosis of the Conjunctiva," makes this very emphatic pronouncement:

That many of those subject to phlyctenules give evidence of the existence of tuberculous infection in some portion of their tissues is no evidence that the conjunctival lesion is also tuberculous, and until some responsible observer has demonstrated the presence of the tubercle bacillus in an extended series of phlyctenules, I see no valid reason for regarding phlyctenular conjunctivitis, *per se*, as a form of tuberculosis of the conjunctiva.

* Read before the Section on Ophthalmology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

1. Eyre, John W. H.: *Lancet*, London, 1912, i, 1319.

Dr. L. V. Hamman, chief of the Phipps Tuberculosis Dispensary of the Johns Hopkins Hospital, and one of the authors of Hamman and Wolman's authoritative work, "Tuberculin in Diagnosis and Treatment," in conversation with me, has expressed a similar view. The substance of his statement was that if the phlyctenules are a tuberculous manifestation they certainly *sometimes* should show the presence of the tubercle bacillus; otherwise the theory that they are of tuberculous origin is without warrant. He also drew attention to the fact, as bearing on the contention that the phlyctenules are a pseudotuberculous manifestation due to the toxins of the tubercle bacillus, that this view of the action of toxins is rapidly losing ground, and that very many pathologic lesions formerly accounted for in this way have since been proved to be due, not to the action of toxins, but to the presence in these lesions of the bacteria themselves.

Let us now take up in order the evidence on which the doctrine of the tuberculous nature of phlyctenular ophthalmia rests.

1. *The frequency with which the subjects of phlyctenulosis give a positive reaction to the von Pirquet and other diagnostic tuberculin tests.*

To this evidence the advocates of the doctrine can hardly attach much weight, since Hamburger of Vienna and others have shown that about the same percentage of positive reactions to the von Pirquet test is encountered in healthy persons as has been found in those with phlyctenulosis. On this point Eyre, already quoted, says:

I have come to regard a positive reaction to these [tuberculin skin] tests when occurring in an individual more than 1 or 2 years old as quite useless for purposes of diagnosis.

And, just as emphatically, Hamman and Wolman² say:

A positive reaction [to von Pirquet's test] is of considerable value in diagnosis during the first year of life, of less during the second, of little in childhood, and of none in adult life.

It is, perhaps, hardly necessary to remark that, in the absence of definite evidence of clinical tuberculosis, no competent and conscientious physician would feel himself warranted in employing tuberculin therapeutically, simply because the von Pirquet test elicited a positive reaction.

2. *The efficacy of tuberculin in the treatment of phlyctenulosis, especially in chronic cases and in preventing recurrent attacks of the disease.*

It has not been possible for me to make even an approximately thorough study of the extensive literature of the past few years dealing with the theory of the tuberculous nature of phlyctenular ophthalmia. Two important papers published in this country, however, which together include a summary of the results obtained in ninety cases of phlyctenulosis treated with tuberculin, seem to afford fairly conclusive evidence as to the efficacy of this treatment.

Fifty of these cases were reported by Dr. Richard J. Tivnen³ of Chicago in a paper read before the Section on Ophthalmology of the American Medical Association in 1911. It is to be regretted that, though

the author in the tabular report of these cases heads a column "Therapeutic Duration of Treatment," he gives under this heading only the date when the treatment was *begun*, and does not in a single instance mention its *duration*. Measurably to offset this omission, however, he states elsewhere that the shortest period of treatment of any case was "about three weeks," and the longest six months.

Turning to the column in which the duration of the disease before treatment was begun is given, we find that eleven of the fifty cases had existed three months or less. Of these only two had lasted this long, five were of two months' duration, one of six weeks, one of one month, one of two weeks, and one had existed only two days. None of these cases can be regarded as chronic in character, and that not one of them, not even that of two days' duration, was cured in less than "about three weeks" seems to afford but poor evidence of the value of the treatment employed. Indeed, when it is borne in mind that in addition to the administration of tuberculin the usual ocular treatment, such as yellow oxid of mercury, atropin, etc., was employed, that constitutional measures, such as regulation of the diet and hygienic conditions, were not overlooked, and further that "tonics" were administered, it is difficult to escape the conviction that the tuberculin was a definite handicap to the other very proper therapeutic measures, and that the results would almost surely have been more satisfactory had it not been employed. It may be added, as of interest, that in only six of the cases (12 per cent.) was there a history obtained of either active or latent tuberculosis.

The other paper referred to was by Davis and Vaughan,⁴ published in September, 1912. Like Dr. Tivnen, they also head a column in their tabular summary of forty cases of phlyctenular ophthalmia treated with tuberculin "Therapeutic Duration of Treatment," but, under this head, mention only when the treatment was begun. For this they make partial amends by stating, in another part of their paper, that the duration of treatment varied from "a few weeks" to eight months.

It is interesting to note that of the forty cases the result of the von Pirquet test was positive in only twenty-seven (67.5 per cent.), and was negative in thirteen cases (32.5 per cent.), hardly as large a percentage of positive results as might be expected in the same number of healthy persons.

Turning to their column showing the duration of the disease before treatment, we find no less than fourteen cases (35 per cent.), in which this is given as two months or less. Of these the duration of four was two months, three "off and on" for two months, four one month, one two weeks, and two one week. The same comment applies to these cases as to the acute cases of Dr. Tivnen's table. It seems remarkable that not one of these comparatively recent cases was cured in less than "a few weeks." That their results were even less favorable than those of Dr. Tivnen is doubtless accounted for by the fact that they employed no constitutional treatment but tuberculin and "but little local treatment," atropin having been used in but two cases. It may be added, as worthy of note, that but *one* of their cases showed

clinical signs of active or inactive tuberculosis—tuberculous glands of the neck being present in this case.

One of the best-equipped and most careful students of ocular tuberculosis in this country, Dr. George S. Derby of Boston, has probably had as large an experience with tuberculin in the treatment of phlyctenular ophthalmia as any one in America, and he has expressed his views very plainly as to its value in this condition. In discussing Dr. Bruns' paper on "Phlyctenular Ophthalmia and Its Etiology," in the Section on Ophthalmology of the American Medical Association, at Atlantic City, in June, 1912, he said:

I have had considerable experience with tuberculin in the treatment of these [phlyctenulosis] cases during the past five years, and I feel doubtful whether any of the cases have been much benefited by it.

And, again, in discussing Dr. Will Walter's paper, "Phlyctenular Ophthalmia and Episcleritis," before the same Section, in 1913, he said:

The use of tuberculin in phlyctenular disease is not often necessary. Most of these patients recover without tuberculin. Even though tuberculin is used, it is often extremely difficult to prevent repeated attacks in obstinate cases. . . . It is not nearly so important as general hygiene.

I have taken the liberty of italicizing this observation of Dr. Derby as to the inefficacy of tuberculin in preventing repeated attacks in obstinate cases of phlyctenulosis, for it is to be borne in mind that its efficacy in accomplishing just what Dr. Derby's experience shows that it does not accomplish has been cited as one of the proofs of the tuberculous nature of phlyctenular ophthalmia.

3. *The development of phlyctenular conjunctivitis and keratitis after application of tuberculin to the eye and after other diagnostic tuberculin tests.*

On this point Hamman and Wolman⁵ say:

In several thousand [ocular] instillations [of tuberculin] we have had but two untoward results, one patient developing phlyctenular conjunctivitis, which subsequently completely healed, the other, an episcleritis, which also healed, and which we are not sure was due to the test.

In my own mind there is little doubt that had the instillations in these several thousand eyes of persons whose condition seemed to demand a tuberculin test consisted of a 2 per cent. solution of silver nitrate or copper sulphate, a considerably larger number of phlyctenular cases would have developed; for every one of large experience in the management of ocular maladies has seen cases of phlyctenular keratitis or conjunctivitis which were provoked by the application of unduly severe remedies to the eye, and I can recall others in which the attack followed a slight traumatism, such as an abrasion of the cornea or bulbar conjunctiva.

Some who teach the tuberculous doctrine of phlyctenulosis hold that "some external, local stimulant is necessary to bring out the phlyctenules." If this view is correct, why, would ask, should not the tuberculin employed in the Calmette test, acting simply as a stimulant or irritant, occasionally produce this effect?

It is, perhaps, not so easy to explain satisfactorily the development of phlyctenules after the skin or subcutaneous tuberculin tests. It is to be said, how-

ever, that this is an unusual occurrence, and it may be questioned whether it ever happens, except in persons whose systemic condition is such that an outbreak of phlyctenulosis may be regarded as imminent. Under such circumstances it is readily conceivable that any added constitutional disturbance, such as the systemic effect of tuberculin, or that which might follow the ingestion of unwholesome food, may turn the scales, and precipitate the ocular inflammation, just as, under like circumstances, the application of any irritant to the eye may do.

4. *The occasional occurrence in phlyctenular ophthalmia of focal reaction following diagnostic or therapeutic injections of tuberculin or after the von Pirquet test.*

Dr. Tivnen in his paper, already quoted, mentions the occurrence of focal reaction after the von Pirquet test in four of his fifty cases of phlyctenulosis, but describes the reaction in three of these as being "slight." Drs. Davis and Vaugan in their forty cases mention three instances of focal reaction, one of these being "slight." If we interpret, and this seems not unwarrantable, the three "slight" reactions of Tivnen's series and the one of Davis and Vaugan's as "doubtful," we have in the combined series of ninety cases but three definitely positive focal reactions—a percentage of only 3.33. Although I am aware that it is not in accord with the commonly accepted view, I cannot persuade myself that any constitutional disturbance comparable to that produced by the von Pirquet test would not have influenced unfavorably the ocular inflammation quite as often and quite as markedly as happened in these ninety cases after the tuberculin test.

It is worthy of remark that in neither of the papers in question is there mention of focal reaction having resulted, in a single instance, from the *therapeutic injection of tuberculin*. If such reactions had been observed, it seems most improbable that they would not have been recorded as evidence in favor of the authors' views regarding the etiology of phlyctenular ophthalmia; if no such reactions occurred, the circumstance is certainly of much significance.

5. *The chronicity and tendency to recurrence of phlyctenular ophthalmia; its predilection for the poorly nourished and for those in whom the existence of the so-called strumous or scrofulous diathesis is manifest, and the glandular complications which frequently accompany it.*

As is universally recognized, phlyctenular ophthalmia is essentially a disease of childhood. In the exceptional cases encountered in adults it will generally be found that the affection first manifested itself in childhood, and has recurred from time to time in after years. These, in my experience, are the cases in which the "scrofulous" diathesis, the glandular complications, and not infrequently, I am willing to admit, definite clinical signs of tuberculosis, are found. On the other hand, the much larger number of cases encountered in childhood, which commonly respond promptly to treatment, and which, if they recur at all, do so only during childhood, do not show, or, at all events, very rarely show, any signs of scrofula or tuberculosis. These are the cases, I contend, which must be regarded as typical, and it is from the study of these cases that we must draw conclusions as to the etiology of the affection, and not from the exceptional and atypical cases encountered in adult life.

5. Hamman and Wolman: *Tuberculin in Diagnosis and Treatment*, p. 209.

What, then, does the study of these cases of childhood show? In the first place, it may be said that the children brought to our clinics with phlyctenulosis are usually not puny and ill nourished; on the contrary, they are commonly well nourished, and not infrequently have ruddy cheeks. Nine times in ten we find, as evidence of systemic disorder, in addition to the ocular inflammation, facial eczema, eczema perhaps elsewhere, and very often an eczematous nasal catarrh. On inquiry it will be learned that they are fed on nearly everything that a child should not eat, and that they are much too closely confined in rooms or dwellings that are thoroughly insanitary. Further, it will often be found that their tongues are furred, their bowels in a torpid condition, and that their stools are foul-smelling.

Perhaps I have already said enough to make it evident that I am a firm believer in the view formerly held by most ophthalmologists, and especially by German ophthalmologists, that phlyctenular ophthalmia, certainly as it is encountered in children, is an ocular eczema, and that it has just as much, and just as little, to do with tuberculosis as has the facial eczema which is its usual accompaniment.

Like the attendant eczema, phlyctenulosis is certainly the result of an endogenous infection, and without doubt—in my mind, at all events—this infection is from the alimentary canal—intestinal intoxication, as it is phrased nowadays. The investigations of Weeks and others, who have usually found the *Staphylococcus aureus* or *albus* present in the phlyctenules, as well as in the eczematous nodules, make it clear that these are the micro-organisms which, having gained entrance to the blood-stream, are commonly responsible for both the skin and the ocular lesions.

How much significance should be attached to the frequent presence of indican in the urine of those suffering with phlyctenular ophthalmia I do not pretend to decide; but investigators who do attach importance to this symptom, and who look for it systematically, report its presence, in large or moderate amounts, in nearly every case of the disease.

If there is any tuberculous affection—or, if you please; pseudotuberculous affection—that responds to local and constitutional treatment in the prompt manner that phlyctenular ophthalmia commonly does, I do not know of its existence. Certainly, true ocular tuberculosis shows no such response, even though tuberculin be employed; on the contrary, it is very intractable and difficult to control.

There are, indeed, few ocular maladies, in my experience, more amenable to judicious therapeutic measures than phlyctenular conjunctivitis and keratitis, and especially is this true of the many cases occurring in childhood. The measures which I employ are regulation of the patient's diet and habits of life, an energetic purgative, which should contain calomel, given at the outset and repeated, perhaps, in forty-eight hours, followed by the administration of syrup of the phosphates of iron, quinin and strychnin—rather than the commonly prescribed syrup of the iodid of iron—and atropin and yellow oxid of mercury ointment as routine local applications. I may add that I feel not a little "disgruntled" if the majority of my patients are not well in considerably less than three weeks.

CONCLUSIONS

The evidence adduced in support of the doctrine that phlyctenular ophthalmia is a tuberculous or pseudotuberculous lesion is far from convincing.

The frequency with which the subjects of phlyctenulosis give a positive reaction to diagnostic tuberculin tests is of little significance in view of the fact that the same tests show a scarcely smaller percentage of positive reactions in healthy persons.

There is excellent authority for the contention that "until some responsible observer has demonstrated the presence of the tubercle bacillus in an extended series of phlyctenules," or, at least, until it has been shown to be sometimes present, the assertion that the affection is, in any sense, tuberculous is without warrant.

In the present state of our knowledge of the etiology of phlyctenulosis, the employment of tuberculin as a therapeutic agent in this affection is unjustifiable, not only because the ill-considered use of tuberculin is capable of doing much harm, but also because the clinical evidence shows pretty clearly that, if it is not actually harmful, it surely is not helpful. Definite clinical signs of the existence of tuberculosis, apart from the ocular inflammation, may justify the administration of tuberculin, but even in such circumstances the effect on the eye could be only indirect.

As phlyctenulosis is essentially a disease of childhood, and the typical cases occur not in adult life, but in children, it is from the study of these cases that trustworthy conclusions as to the etiology of the affection are to be drawn. The study of these childhood cases shows, from the almost constant association of facial eczema with the ocular inflammation, that phlyctenular ophthalmia, as was formerly very generally held, is an ocular eczema, due, for the most part, like the facial eczema, to intestinal intoxication, and that tuberculosis is seldom, if ever, an etiologic factor.

Cathedral and Howard Streets.

ABSTRACT OF DISCUSSION

DR. W. E. GAMBLE, Chicago: It is most timely that Dr. Theobald has called our attention to this subject in the way he has. I believe the use of tuberculin in phlyctenular disease is not justified. In my hands, patients get well without tuberculin as quickly as with it. That this disease is tuberculosis is largely speculation. We are no nearer to-day knowing the etiology of these cases than we were forty years ago. There is some basis for the conclusion that this is ocular eczema, and yet we see cases with palpable cervical glands as the only comitant. The only cases of this disease that might possibly warrant the use of tuberculin would be when large, soft cervical glands, i. e., tuberculosis glands are present.

DR. A. E. DAVIS, New York: While the tubercle bacillus is not yet known to be the direct cause of phlyctenular ophthalmia, yet the tuberculotoxins are capable of causing the trouble. Phlyctenular ophthalmia is the result of some grave constitutional dyscrasia, and is not a simple affection of the eyes brought about by intestinal intoxication, and curable in a few days by regulation of the diet and the patient's habits, the giving of calomel and tonics, and local treatment with atropin and yellow mercuric oxid ointment. It is a grave disease, so far as sight is concerned; and, while the prognosis is favorable so far as concerns any single attack it is rendered unfavorable, as a whole, by the frequent recurrences.

In persons who have had many recurrences of conjunctivitis eczematosa the corneae often bear signs of past

attacks. Thus the sight is impaired, squint or myopia often develops, and children fall behind in development. A frequent outcome is secondary blindness, often many years after the inflammation has passed, representing the after-results of the corneal scars with inclusion of the iris.

1. Dr. Theobald entirely overlooks the fact that many healthy persons are infected with tuberculosis. Hamburger has shown by post mortem on 848 children, that "from newborn infants up to 14 years, an average of 40 per cent. had been infected. Infection up to 3 months of age in only 4 per cent., steadily increased with age until from 11 to 14 the percentage reached 70. The distinction between infection and clinical disease in these cases is important. It is significant that phlyctenular ophthalmia is rarely seen in children under 1 year. Stomach disturbances are most frequent up to this age, while tuberculous infections are fewest. Stomach troubles, therefore, seem not to be the true cause.

2. In the forty cases in which Dr. Vaughan and myself reported "cures" only after a "few weeks" treatment, even in acute cases, we continued the treatment, after the phlyctenules had disappeared, to prevent recurrences. The phlyctenules would often disappear in a few days, but no case is really cured until the patient reaches maturity, and sometimes not then.

3. Focal reaction to my mind is positive evidence of the tuberculous nature of the disease. This is most impressive, when, following the primary reaction of a diagnostic dose, the phlyctenules on the third or fourth day melt away as by magic. These patients should not be considered cured on the first disappearance of the phlyctenules, and subsequent smaller doses should be given to complete the cure.

Dr. Theobald thinks it significant that neither Dr. Tivnen nor Dr. Vaughan and I observed a single instance of focal reaction in the ninety cases reported by us, from the therapeutic injection of tuberculin. Dr. Vaughan and I purposely refrained from giving too large therapeutic doses, in order to avoid decided reactions. Focal reaction to tuberculin injections can be explained on no other ground than as the action of a true antigen on the specifically tuberculous diseased eye.

4. He who does not believe in the administration of tuberculin until the clinical signs of tuberculosis are present, fails to recognize the most essential feature of the tuberculin treatment. I would just as soon delay treatment in a suspected case of syphilis, after a positive Wassermann, until clinical signs of that disease appeared.

DR. GEORGE H. DERBY, Boston: With regard to the necessity of showing the tubercle bacillus in the phlyctenules, I will remind you of the difficulty of finding the tubercle bacillus in chronic tuberculosis of the eye. Certainly the tubercle bacillus which may be responsible for phlyctenule is very different from the tubercle bacillus responsible for acute tuberculosis of the eye and also in chronic ocular tuberculosis. The pathologic picture is atypical, but the fact that it is not typical does not prove that these lesions may not be tuberculous. I have seen a few cases in children starting as a phlyctenular keratitis and later on becoming a deep-seated, chronic ocular tuberculosis. I recently talked with one of the social workers of the Massachusetts Charitable Eye and Ear Infirmary to whom the phlyctenular cases had been assigned on account of her previous experience in a tuberculosis hospital. She called attention to the fact that in a large percentage of the families she visited in which there was phlyctenular disease, one or more members of the family showed tuberculosis. Even if we are not sure that phlyctenular disease is actually due to tuberculosis it would be better if we assumed that it was, because the problem is essentially the problem of tuberculosis. If the children are treated as tuberculous they recover much more quickly and it is better for all concerned. In long-standing cases that are resistant and show repeated attacks of the disease, there is nothing better than sanatorium treatment. If the patients can be sent to a sanatorium for three, six or nine months they come back entire, different children and are more apt to be free from the disease afterwards.

DR. HARRY VAUGHAN, Morristown, N. J.: I wish to say concerning the point that the germ cannot be found in the lesion, that the products or ferments of tuberculosis do not digest surrounding tissues, as do the products of the staphylococcus, streptococcus and other bacteria. I think that fact makes it difficult to find the germ. Possibly the germ is not present, but the by-products cause the lesion. We do not give the tuberculin treatment to every child. We study our cases carefully to see whether tuberculous symptoms predominate. We examine the glands and take the temperature, and surely the local, the focal and the constitutional effect of the tuberculin test must mean something. We have had cases in which in twenty-four hours the lesions would be lighted anew. In many instances we could find tuberculosis in two or three generations. I really believe when tuberculous symptoms predominate, when we have a local, focal and constitutional von Pirquet, with large glands and a tuberculous history, tuberculin will be found to be not a sovereign remedy, but a great help, as much so as the Flexner serum in meningitis. It has not cured all the cases but it has reduced the mortality. So with tuberculin.

DR. RICHARD J. TIVNEN, Chicago: Dr. Theobald is correct when he insists that every item of Koch's law be fulfilled before the tuberculous etiology of phlyctenulosis be accepted. Some, however, are unwilling, even in the absence of direct confirmation, lightly to cast aside the clinical evidences exhibited by these cases, which suggest some type of tuberculous origin. The symptom-complex exhibited by these cases, the clinical course of the malady, its predilection for the poorly nourished, its glandular complications, its association with tuberculous processes in other parts of the body, its tendency to recurrence, its response to tuberculin—strongly support the theory of tuberculosis, even though alone they are not conclusive. What positive proof is at hand conclusively to determine that phlyctenulosis is produced by intestinal intoxication alone? That the tuberculous theory has not as yet been scientifically established is not a reason for ignoring all the strongly suggestive evidences in its favor. There are many reasons why final judgment on this question should be withheld. We still have much to learn in our clinical observations and interpretations, and particularly in our laboratory diagnoses. May it not be that the refinements of diagnosis necessary in this investigation have not been sufficiently exhausted; that some anatomic variation of the ocular tissue presents peculiarities not yet recognized or understood; that some vagary of the invading organism presents difficulties in the way of establishing its identity; and may not the tuberculous process itself exhibit vagaries which we are unable, with our present methods of investigation, to discover? Is it wise, therefore, lightly to cast aside a theory of etiology which has considerable evidence in its favor, simply because it lacks confirmation? Dr. Theobald refers to eleven cases which my table reports as existing "three months or less" and, applying my statement that none were cured in less than three weeks, observes that it "affords but poor evidence of the value of the treatment employed," and further that because other constitutional and local measures were also used, it is difficult to escape the conviction that the tuberculin was a definite handicap to the other therapeutic measures, and that the results would almost surely have been more satisfactory had it not been employed. Many difficulties surrounded the treatment of my cases; the patients were mostly ambulatory and a regular, systematic plan of treatment was impossible. It may thus be understood why many of them failed to show improvement in less than three weeks. Dr. Theobald will see, in my final report of these cases, that not one of the eleven failed to show improvement and five of them were listed as "cured." These results are fully as satisfactory as the usual methods advocated that fail to check the recurrences of this disease, which are the crux of the problem, for with each recurrent attack, perceptible inroads on the patients' visual acuity results.

In view of the almost absolute failure of the present treatment to prevent recurrences of this disease, the advocates of the tuberculous theory feel the need of a more definite

plan of therapeutics and believe that sooner or later the theory of tuberculosis as the dominant etiologic factor in the disease will be recognized, and that tuberculin will constitute the essential therapeutic agent in its treatment.

DR. WALTER B. WEIDLER, New York: I spoke on this same subject at Minneapolis when discussing Dr. Davis' paper, and I wish again to put myself on record as believing thoroughly in the use of tuberculin from my experience in the Manhattan Eye and Ear Infirmary. I think the attitude assumed by Dr. Theobald with regard to phlyctenulosis is unfortunate. Three years ago Dr. Bruns thought none of these cases were tuberculous. Dr. Tivnen thinks that almost all of them are and Dr. Theobald that probably few or none are. I think the fact that the tubercle bacillus cannot be demonstrated is a poor argument. Dr. Gamble says he would be willing to use tuberculin in cases with enlarged glands. As far as I know, the tubercle bacillus has been demonstrated in these glands before they have broken down and pus has formed. My feeling is that in cases of phlyctenulosis with recurrences the majority of the patients will give a history of tuberculosis in some member of the family if we will only take the trouble to trace it back. That has been my experience in my work at the Manhattan. At present I believe that many of these cases are due to a toxin or an endotoxin from a tuberculous focus somewhere else in the body, not of necessity in the eye. In the eye we can readily see the manifestation of any tuberculous process in other tissues of the body. The one reason that so many do not believe in tuberculin therapy in these cases is that they do not follow their cases long enough. I have seen probably three hundred cases in the last three years. They will recur, but my feeling is that with tuberculin we produce an indefinite immunity, and just how long it lasts we do not know. With a tuberculous tendency and inheritance I do not believe we can eradicate it by one course of tuberculin treatment no matter what the manifestation is in the eye. I made the statement at the New York Academy of Medicine last winter that when I had a positive von Pirquet I have never failed to cure the lesion, whether a tuberculous choroiditis or iridocyclitis, of which latter we have four under observation at present, or the severest form of keratitis or ulcer of the cornea. Unfortunately this statement must be corrected as I have had, since that time, a youth of 10 with fibrous connective tissue exudate in the pupillary area, which did not absorb under tuberculin treatment but the active iridocyclitis cleared up with the use of tuberculin. This, however, cannot be claimed as a cure due to tuberculin.

DR. THOMAS H. CURTIN, New York: I have seen all of Dr. Weidler's cases and he has seen mine. For the past three years we have been making a systematic study of phlyctenular cases and other cases which we regarded as tuberculous, using usually the von Pirquet test for diagnosis. On the phlyctenular cases over 80 per cent. (in children under 10 years of age) reacted positively to this test. A certain percentage of cases, which, from the general appearance of the patients was due in my opinion to gastrointestinal conditions, did not react. These cases readily cleared up under the use of calomel, rhubarb and soda and yellow mercuric oxid. But we see also the recurrent cases, and some which had been previously treated by the ordinary method did not return when put on tuberculin, showing that the tuberculin treatment had proved more efficacious than the ordinary treatment. I do not believe that all phlyctenular cases are tuberculous, but that phlyctenular conjunctivitis is allied to tuberculosis, as are cases of strumous or scrofulous diathesis. These cases may not be tuberculous *ipso facto*, but dependent on an underlying condition which may be tuberculous and which I believe in 80 per cent. is tuberculous. As Dr. Davis said, the injection of tuberculin into the arm does not mean that the tuberculin is disseminated throughout the tissues of the body, but that it stays at the point of injection and manufactures antibodies which neutralize the toxins of the tubercle bacilli and destroy the tubercle bacilli themselves. In my experience and in the observation of a great many others I have yet to see or hear of any ill effects

produced by tuberculin either in the use of the von Pirquet test or the subcutaneous test for diagnosis or in the administration of tuberculin when properly used for the treatment of any tuberculous disease of the eye. Tuberculin was formerly used in too large doses. We should begin with from 1/80,000 to 1/50,000 mg., gradually increasing, keeping the patients under treatment for from six months to two years. We cannot cure them in a short time, and they should return again at intervals and have the tuberculin injected in order to keep up the production of these antibodies, which is the keynote of the therapeutics.

DR. WILLIAM TARUN, Baltimore: Four facts should be borne in mind in considering phlyctenular ophthalmia: 1. We have no way of making a diagnosis of lymphatic tuberculosis except by the skin reaction or the subcutaneous test. 2. The anatomic structure of the conjunctiva is practically the same as that of adenoids and tonsils. 3. The enlarged glands are caused by the secondary infection by pyogenic organisms. 4. In all cases of phlyctenulae we have intestinal intoxication as indicated by the presence of indican in the urine.

Dr. Theobald has stated that, so far, we have no positive evidence that phlyctens are tuberculous because of the absence of the tubercle bacilli. It is evident that there is a tuberculous basis plus a secondary infection by a pyogenic organism—*Staphylococcus aureus*. To those who are not yet convinced that there is a tuberculous basis I would suggest the study of an article on this work done by Rubert (*Monatsbl. f. Augenheilk.*, September, 1912). It is a continuation of work done by some one else in which he has produced tuberculosis in lower animals, using a normal one as control. Instillations of staphylococcus cultures or toxins into the conjunctival sac of these animals produced phlyctens in a majority of the tuberculous and none in the normal. These phlyctens had the same histologic structure as that of Fuchs. The presence of the tubercle bacillus is not known. As to treatment, tuberculin should be used when we cannot handle the cases in any other way. The initial dose will depend on the reaction by the von Pirquet test. In those cases in which you are afraid to use tuberculin I would suggest the treatment outlined by Dr. Derby—that the cases be sent to a sanatorium. I grant that the treatment as outlined by Dr. Theobald does some good. They are relieved from their symptoms, but they still have a more serious condition remaining—a tuberculosis. A case in point. I was called to see a plethoric, healthy-looking child of 2½ years with a typical phlycten for which I prescribed the usual treatment, but advised the physician that the child had a tuberculosis as the basis of the trouble. Three months later the child died of a tuberculous meningitis. Those of you who do not recognize the tuberculous basis of phlyctenular ophthalmia are not doing all you should do for your patient.

DR. MARK D. STEVENSON, Akron, O.: The one thing that demands challenge in the conclusions of Dr. Theobald is whether or not this disease is tuberculous. This can not be settled; it must be speculative. The elusiveness of the germ is well understood, not being necessary in the lesion. The other symptoms of tuberculosis are present. The full pathology of tuberculosis like that of many other diseases is not entirely written. When it is I think it will be found that phlycten is one of the tuberculous lesions, and the thing that especially appeals to me, although it might be speculative, is that it responds to general tuberculosis treatment. I have seen these conditions respond quickly and I think it would be most unfortunate if the idea should go out from this section that it was at all proved that these lesions are not of a tuberculous nature.

DR. SAMUEL THEOBALD, Baltimore: I still think there are very few maladies of the eyes that respond so promptly and so satisfactorily to treatment as phlyctenular disease. Of course I recognize that there are exceptions to this rule, but it does not strike me that it is a very serious affection. The patients that recover do not take three weeks. The majority are cured within little more than one-third of this time. When recurrences take place this is due, in the majority of cases, to the carelessness of parents or those in charge of patients

AMETROPIA—ZENTMAYER

Jour. A. M. A.
Aug. 15, 1914

in not following out the directions of the medical attendant. I do not think I could have understood Dr. Davis correctly when he said a positive Wassermann reaction and a positive von Pirquet, so far as treatment is concerned, are equivalent. Everybody knows that in the absence of clinical signs of tuberculosis a positive tuberculin reaction does not call for treatment for tuberculosis. It does not mean clinical infection of the system has occurred. On the other hand, a positive Wassermann means syphilis and is a clear indication for antisyphilitic treatment. Dr. Stevenson spoke especially of the elusiveness of the tubercle bacillus. The authorities I have quoted do not pretend to say that the bacillus must be found every time. One says it must be found some times. The other says that, at least, some responsible investigator should find it in a series of cases. After I had written the paper I wrote letters to seven eminent authorities on tuberculosis throughout the country asking their experience as to the association of phlyctenular ophthalmia with tuberculosis. In their replies several spoke of having encountered cases of phlyctenulosis in children in the so-called scrofulous condition, and in association with glandular and bone lesions of a tuberculous nature; but they all agreed that it was seldom found in association with pulmonary tuberculosis. One charge of the Maryland State Tuberculosis Sanatorium. He wrote: "We see surprisingly little phlyctenular disease in association with tuberculosis. We have had only six cases in the past year in handling about eight hundred cases of tuberculosis. Of this number fifty were in children. We have had but three cases among our children."

A STUDY OF THE EFFECT ON HETERO- PHORIA OF THE CORRECTION OF AMETROPIA WITH A CONSIDERATION OF SOME ASSOCIATED CONDITIONS *

WILLIAM ZENTMAYER, M.D.
PHILADELPHIA

This analysis was undertaken to determine the effect on heterophoria of the correction of ametropia. In the development of the paper the relation of other factors to the problem brought in additional data. The opportunity which this afforded of analyzing these correlated conditions was embraced and the results incorporated.

The material used was supplied from my private case-records. No case was used unless at least a month had elapsed between the original and final tests. In more than two-thirds of the cases several years intervened, the second determination being made on the patient's return for a change of glasses. Only cases were used in which there was equal and normal, or better than normal, vision in each eye, and in which no actual deviation of the visual axes existed. No case in which prisms had been worn was considered available. Presbyopia was excluded. Only cases were used in which uniform tests had been employed in the various determinations.

As there is a marked discrepancy between some of the results given here and those heretofore published by other writers, it is well to state the methods employed by me in making the various tests. In testing both the far (6 meters) and the near (1/3 meter) status of the muscle balance a colored Maddox

rod was used, a light 1 cm. in diameter serving for the distant object and a small electric lamp for the near object. Loose prisms or the phorometer, along with the Maddox rod, was used to measure the degree of imbalance for both the vertical and lateral muscles at infinity and the rotary prism at near. Abduction and adduction were determined by loose prisms. In the past few years when a patient with but slight effort reaches an adducting power of 15 degrees it has been

The average hypermetropia in the cases of H + Ah with esophoria for distance and exophoria for near equals 1.50 D.
The average hyperopia in the cases of H + Ah with exophoria for distance and near equals 1.12 D.
The average myopia in the cases of M + Am with esophoria for distance equals 1.87 D.
The average myopia in the cases of M + Am with exophoria for distance equals 2.12 D.

recorded 15+ as experience has shown that these patients readily acquire a high prism adduction by exercise or by knack.
For the purpose of study the cases were divided into groups having like ametropia, and these were subdivided into groups having similar muscle imbalance for distance (Table 2).

TABLE 2.—GROUPS AND SUBGROUPS OF CASES

Ametropia	No. of Cases	Muscle Imbalance for Distance	Per Cent.
H + Ah	236	Orthophoria	10
Ah		Esophoria	62
M + Am	20	Esophoria	28
Amh	87	Esophoria	60
	30	Esophoria	40
Anisometropia	24	Orthophoria	60
		Esophoria	40
		Esophoria	24
		Orthophoria	52
		Esophoria	24
		Esophoria	15
		Esophoria	25
		Esophoria	60

There were 145 cases of H + Ah, with esophoria for distance and exophoria for near. The average esophoria for distance at the first test was 2.5°, and at the final test 1.75°. The average exophoria for near at the first test was 5°, and at the final test 4.5°. Average abduction was 6°, adduction 17°. Hyperphoria in 26 per cent.
There were 66 cases of H + Ah, with exophoria for distance and near, greater for near. Average exophoria for distance at the first test, 1.62°, at the final

* Read before the Section on Ophthalmology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

test 1.5°. Average exophoria for near at first test 8°, at the final test 9°. Average abductions 6.5°, adduction 14°. Hyperphoria in 59 per cent.

There were twenty-one cases of H + Ah with orthophoria for distance and exophoria for near. The average exophoria for distance at the final test was 0.37°. Average exophoria for near at the first test 6.5°, at the final test 6°. Average abduction 6°. Average adduction 17°. Hyperphoria in 40 per cent.

There were thirteen cases of H + Ah in which there was esophoria for both distance and near with a greater degree for near. The average esophoria for distance at the first test was 2°, at the final test 2.62°. The average esophoria for near at the first test was 6.62°, at the final test 3.62°. Average abduction 5.5°. Average adduction 20°. Hyperphoria in 25 per cent.

There were ten cases of H + Ah with esophoria for both distance and near with a greater degree for distance. The average esophoria for distance at the first test was 6°, at the final test 4.62°. The average esophoria for near at the first test was 2.50°. This was converted into an average exophoria at the final test of 0.75°. Average abduction 7°. Average adduction 20°. Hyperphoria was present in 57 per cent.

There were twelve cases of Ah with esophoria for distance. The average esophoria for distance at the first test was 1.37° and at the final test 1°. The average exophoria for near at the first test was 4° and the final 4.5°. Average abduction was 6°. Hyperphoria was present in 50 per cent.

There were eight cases of Ah with exophoria for distance. The average exophoria for distance at the first test was 2.50° and at the final test 1.87°. The average exophoria for near at the first test was 7° and at the final 4°. Hyperphoria present in 50 per cent.

Of eighty-seven cases of M + Am, fifty-six had esophoria for distance and thirty-one had exophoria for distance.

Of the fifty-six cases of M + Am with esophoria for distance the average esophoria at the first test was 2.25° and at the final test 1.50°. The average exophoria for near at the first test was 1.50° and at the final 1.25°. Average abduction 6°. Average adduction 19°. Hyperphoria in 35 per cent.

There were 31 cases of M + Am with exophoria for distance, and greater exophoria for near. The average exophoria at the first test was 2.75°, and at the final test was 3°. The average exophoria for near at the first test was 10°, and at the final test 11°. The average abduction was 7°. Average adduction was 10°. Hyperphoria was present in 61 per cent.

There were 30 cases of Amh. In 16, with esophoria for distance. The average esophoria for distance at the first test was 1.75°, and at the final test 1.62°. The average exophoria for near at the first test was 2.37°, and at the final test 4.75°. The average abduction was 7°. The average adduction 12°. Hyperphoria was present in 20 per cent.

There were 7 cases of Amh with exophoria for distance and near. The average exophoria for distance at the first test was 1.62°, the average at the final test was 62°. The average exophoria for near at the first test was 13°, and at the final test 13°. The average abduction 7°. The average adduction 14°. Hyperphoria was present in 20 per cent.

There were 7 cases of Amh with orthophoria for distance and exophoria for near. The average exo-

phoria at the final test for distance was 0.50°. The average exophoria for near at the first test was 7°, and at the final test 7°. Average abduction was 7°. The average adduction 15°. Hyperphoria was present in 20 per cent.

There were 24 cases of anisometropia, in which the average difference in refraction of the two eyes was 2 D. In 15 there was esophoria for distance. The average at the first test was 2°, and at the final test 1.37°. The average exophoria for near at the first test was 6°, and at the final test 5.62°. The average abduction was 6°. The average adduction was 16°. Hyperphoria was present in 50 per cent.

In 6 cases of Amh there was exophoria for near and far, greater for near. The average exophoria for near at the first test was 2.5°, at the final test 1.25°. The average exophoria for near at the first test was 9°, and at the final test 10°. The average abduction was 7.5°, and adduction 12°. Hyperphoria was present in 40 per cent.

An analysis of these findings with a view of determining the influence of the correction of the ametropia on associated heterophoria shows that: When in H + Ah esophoria existed for far and exophoria for near the esophoria was reduced on the average of 0.75°, or about 33 per cent. of the original amount, whereas the exophoria which was present for near was reduced 0.5°, or 10 per cent. of the original amount, a negligible amount. The esophoria in this status of the muscles has been held by some to be an apparent esophoria, the real difficulty being an insufficient convergence power. The correction of the H + Ah would tend further to reduce the positive portion of convergence, and we might expect to find the exophoria for near, at least, somewhat increased; but it remained practically unchanged. The esophoria, however, was reduced, rather indicating that it arises from the convergence associated with the accommodation required for distinct distance vision.

When exophoria existed for both distance and near with a greater amount for near, practically no change occurred in the distance exophoria, and the exophoria for near was increased 1°, or 12 per cent. of the original amount. Here we have a convergence insufficiency with a beginning divergence excess, and the correction of the H + Ah would tend to increase the exophoria for near by reducing the call on the accommodation. Practically the only cases calling for prism exercise fell within this group. Almost all were relieved of symptoms, and in nearly all of those in which the exophoria was not greater than 2° for distance, it was either overcome or a low esophoria was established; but this did not persist for any great length of time after the prism exercise was discontinued. The relation of prism abduction and adduction was in almost every instance 1:2 (6:13), not very different, however, from those in which prism exercise was not required (6:15).

When orthophoria existed for distance and exophoria for near, an average exophoria of 0.37° developed for distance, and the exophoria for near increased 2°, or 33 per cent. of the original amount.

Here we have practically the same condition and the same result as in H + Ah with exophoria for distance and a greater exophoria for near.

When esophoria existed for both distance and near, but was greater for near, the esophoria for distance decreased on the average 0.62°, or 33 per cent. of the

original amount, and the esophoria for near was decreased, on the average, 3° , or 45 per cent. of the original amount.

These are cases of convergence excess in which the esophoria for near is decidedly decreased by correction of the $H + Ah$.

When esophoria existed for distance and near, but was greater for distance, the esophoria for distance decreased, on the average, 1.37° , or 23 per cent. of the original amount, and the esophoria for near was converted into an exophoria of 0.75° , a change of 133 per cent.

This group represents a convergence excess with a relative divergence insufficiency, the correction of the ametropia markedly decreasing the esophoria for near.

In Ah with esophoria for distance, the correction of the ametropia had no effect on either the distance or near heterophoria.

In Ah with exophoria for distance, the exophoria for both distance and near was appreciably diminished, probably the result of the improvement in vision from the correction of the astigmatism.

When in $M + Am$ esophoria existed for distance and exophoria for near, the esophoria for distance was reduced 0.75° , or 33 per cent. of the original amount, and the exophoria for near was reduced 0.25° , or 16 per cent. of the original amount.

The cases in this group are largely accommodative convergence insufficiency without the later-imposed divergence excess. The decrease in the esophoria for distance was due to the beginning development of a divergence excess, 16 per cent. of the cases showing a change from esophoria to exophoria, and 50 per cent. a decrease in the esophoria for distance. The average exophoria for near was but little influenced, but the cases showing a moderate amount of exophoria for near at the first test nearly all showed an increase in the exophoria.

When in $M + Am$ exophoria existed for distance and for near, the exophoria for distance was reduced 0.25° , or 9 per cent. of the original, and the exophoria for near was increased 1° , or 10 per cent. of the original.

In this group there was a convergence insufficiency and a divergence excess, the elements making for the development, in time, of a divergent strabismus. The average change was so slight, however, as to indicate an arrest of this progress, although in a few cases it had made advances.

When in Amh esophoria existed for distance and exophoria for near, the esophoria remained practically unchanged and the exophoria for near increased 2.37° , or 100 per cent. In this group the slight esophoria for distance which was present may be considered a static condition. The exophoria increased to a marked degree, and this may be due to the accommodative effort occurring in the course of the altering refraction which these cases undergo.

When in Amh , exophoria existed for distance and for near, but was greater for near, the exophoria for distance was reduced 1° , or 60 per cent. of the original, and the exophoria for near remained unchanged.

When orthophoria existed for distance and exophoria for near, exophoria of 0.50° , or 60 per cent. of the original, developed, and the exophoria for near remained unchanged.

These two groups show but little change, probably because these cases showed little change in the refraction

in the very few cases in which an opportunity had been presented to re-refract after the lapse of time, and a disturbance of the relation between accommodation and convergence was not induced by the correction of the refraction error. When the few cases were assembled into three groups, the number in each was so small that deductions were difficult to make.

When in anisometropia esophoria existed for distance and exophoria for near, the esophoria for distance decreased 0.50° , or 25 per cent. of the original, and the exophoria for near was practically unchanged.

When in anisometropia exophoria existed for near and distance, but greater for near, the exophoria for distance decreased 1.25° , or 50 per cent. of the original, and the exophoria for near increased 1° , or 11 per cent.

These cases showed no greater degrees of heterophoria than the other forms of ametropia, and were little changed by the correction of the error of refraction, except that those showing exophoria for distance had this decreased by equalization of the visual acuity of the two eyes.

In a short series of cases such as was here analyzed, it is possible for a few cases of marked heterophoria to produce an average relatively too high or vice versa. It was thought that this might, in a measure, be a possible source of error, and be neutralized by giving the percentages, in the two main groups, $M + Am$ and $H + Ah$, of cases showing a similar change. These groups were further analyzed to determine the relation existing between the abducting power and the distance imbalance.

Of the cases of $H + Ah$ with esophoria for distance and exophoria for near, in 25 per cent. there was an increase in the esophoria, the average being 2.37° , and the greatest 4° . In 57 per cent. there was a decrease of esophoria, the average being 2° , the greatest 9° . In this series there was a much larger number of cases showing an appreciable decrease of esophoria than was the case in other of the H series. The average abduction equaled 6° . In 30 per cent. in which it was above the average, the esophoria equaled 2.37° . In 70 per cent. in which it was below the average, the esophoria equaled 2.62 per cent. In a series in which abduction was 5° or below the average, esophoria equaled 3.5° , and in a series in which it equaled 7° or more than the average, esophoria equaled 1.75° .

Of the cases of $H + Ah$ with exophoria for distance and near, in 35 per cent. there was an increase in the exophoria. The average was 1.37° , and 40 per cent. showed a decrease, the greatest being, 2° , the least 1° .

The average abduction was 6.5° . In 50 per cent. it was above the average, and in 40 per cent. it was below the average, but in both the average exophoria equaled 1.5° . In a series in which it was 5° or below, the average exophoria for distance was 3.5° .

Of the cases of $M + Am$ with esophoria for distance, in 30 per cent. there was an increase in the esophoria, the average increase was 1.12° , and the greatest was 3° .

Abduction was below the average in esophoria associated with ametropia of any form, and was of equal degree both in the myopic and hyperopic groups.

Abduction was above the average in exophoria associated with ametropia of any form, and was about equal in exophoria for distance both in the hyperopic and the myopic groups.

Abduction was above the average and of equal degree in Amh, no matter what the distance balance.

In 45 per cent. there was a decrease; the average was 2.25°, the greatest 7°.

From the frequency with which right hyperphoria occurred in the foregoing cases, it was evident that right hyperphoria prevailed to a marked degree. As in a tabulation of one hundred cases on another occasion the percentage of right hyperphoria was found to be about 70 per cent., a further series of 200 cases, none of which had been employed in the previous computations, was used. In 105, or 52 per cent., there was orthophoria for the vertical muscles. In 95, or 48 per cent., there was hyperphoria. In 76 per cent. of these it was R. H., and in 24 per cent. L. H. As in making the tests the rod had been invariably placed before the right eye, it was thought that this might in some way be the cause of the preponderance of R. H., but Dr. Holloway found the same preponderance of R. H. when the rod was placed in front of the left eye. Possibly the fact that the right eye is usually the dominant eye is a factor. Forty-six per cent. of H + Ah, 50 per cent. of Ah, 53 per cent. of M + Am, 40 per cent. of H, 38 per cent. of Amh and 50 per cent. of anisometropia showed hyperphoria.

In 74 cases (78 per cent.) it was less than 1°, in 38 cases (40 per cent.) it was 1.4°, in 9 cases (9.5 per cent.) it was 1°, in 3 cases (3 per cent.) it was 1.5° and in 5 cases (5 per cent.) it was 2°. In 4 cases (4 per cent.) it was over 2°. It was found that in less than 1 per cent. was the hyperphoria appreciably altered by correction of the ametropia.

Hyperphoria was present more often in exophoria for distance than in esophoria for distance in the proportion 46:36. It was least frequent and occurred in the same ratio (20 per cent.) in all forms of heterophoria associated with Amh.

CONCLUSIONS

On the whole, it cannot be said that the correction of ametropia greatly influences the associated heterophoria, some of the change here noted being the result of the natural progress of such associated conditions, as evidenced by the fact that a study of a series in which but two weeks intervened between the tests before and after the ametropia had been corrected showed even less change. In a short series of H + Ah with esophoria for distance, exophoria first test 1.37°, final test 1.25°; exophoria for near, first test 6.5°, final test 6.5°.

Considering only the heterophoria, it may be said that the correction of the ametropia reduces the esophoria for distance when associated with H + Ah, and tends to increase the exophoria for near.

When esophoria exists both for distance and near, the heterophoria at both distances will be reduced and the esophoria for near may be converted into an exophoria. Esophoria for distance and likewise an exophoria for near will be reduced by the correction of M + Am.

Exophoria for distance and near will be practically unchanged by the correction of a coexisting M + Am.

Esophoria for distance will be little changed or may go over into an exophoria by the correction of an associated Amh. An exophoria for near, under like conditions, will be increased.

Exophoria for distance in anisometropia will be decreased by the correction of the ametropia.

In no group of cases did the average abduction exceed 7°; the average in all groups was 6.5°.

Hyperphoria occurs in less than 50 per cent. of cases of ametropia. It is somewhat more frequent in H + Ah. In more than three-fourths of the cases it is less than 1°, and in less than 10 per cent. it is 2° or more. Right hyperphoria vastly predominates.

1819 Spruce Street.

ABSTRACT OF DISCUSSION

DR. A. E. DAVIS, New York: The value of Dr. Zentmayer's observations are added to also from the fact that the tests have been uniform, have been made by one surgeon and the cases are from private practice, insuring a greater degree of intelligence and help from the patient than can possibly be obtained from hospital subjects. It seems to me that Dr. Zentmayer does not give himself due credit, nor does he attach enough importance to the influence that the proper correction of ametropia has on heterophoria. In his conclusions, he says: "On the whole, it cannot be said that the correction of ametropia greatly influences the associated heterophoria, etc. Turning to the body of the paper and looking at that group of cases of H and Ah (by far the largest group in the series, 145 cases), in which there was an associated esophoria for the distance and an exophoria for the near, we find that the correction of the refraction reduced the esophoria in the average $\frac{3}{4}$ of a degree, or about 33 per cent. of the original amount, whereas the exophoria which was present for near was reduced $\frac{1}{2}$ degree, or about 10 per cent. of the original amount, a negligible amount." Now I hold that an improvement of 33 per cent. in the esophoria for far and 10 per cent. in the exophoria for near, both of which improvements are in the direction of orthophoria, is a very important factor in helping to bring about relief from asthenopia, if the asthenopia is due to the so-called muscle imbalance. Again, in other groups, "when esophoria existed for both distance and near, but was greater for near, the esophoria for distance decreased on the average 0.62 degrees, or 33 per cent. of the original amount, and the esophoria for near decreased, on the average, 3 degrees, or 45 per cent. of the original amount." Take another group of cases reported by Dr. Zentmayer, H, plus Ah, in which esophoria existed both for distance and near, but was greater for distance, the esophoria for distance decreased, on the average, 1.37 degrees, or 23 per cent. of the original amount, and the esophoria for near was converted into exophoria of 0.75 degree, a change of 133 per cent.! Certainly this is a remarkable change, and the influence exerted by the glasses a most decided one. And when we take into consideration that Dr. Zentmayer recorded no higher degree of esophoria than 15 degrees (when it was higher than 15 degrees, he simply added a plus sign to it) this improvement in these cases as measured by other standards would be greater still. While it must be admitted that in some of the subgroups, especially in the myopic cases, the improvement in the direction of orthophoria is small, or even in the opposite direction, yet, on the whole, and particularly in H Ah, and in anisometropia, the class of cases in which asthenopia is most often present, the influence of glasses on the associated heterophoria is decided and in the right direction, for the most part, that is, towards orthophoria. Landolt has justly emphasized, in all his writings, the necessity of a greater quantity of latent reserve force in the muscles of orientation of the eyes than even for the muscle of accommodation, if we may expect the eyes to be used for a long time without fatigue or without asthenopic symptoms appearing. Hence, any factor that tends to increase this reserve force in the muscles of orientation, as the adjustment of correcting glasses, plays a most important rôle in the relief of asthenopia. Dr. Roosa held to the view that, when the refractive errors were corrected by the adjustment of the right glasses, muscle insufficiencies, in the vast majority of instances, corrected themselves, especially in cases of H and H astigmatism and anisometropia. He placed little or

no reliance on prism exercises in these cases, and I must say that my experience coincides with this view. I would mention one other important factor in the treatment of heterophoria, that is, the giving of tonics and looking after the general welfare of the patient. With these two features of the treatment carried out faithfully, rarely indeed is it necessary to prescribe prisms or to operate on the ocular muscles in any degree of latent insufficiency short of manifest deviation.

DR. HIRAM WOODS, Baltimore: There is a form of esophoria which, in my experience, is usually lessened or modified by refraction correction. Esophoria may be due either to defective action of the externi or overaction of the interni. The average abduction or prism power of the external rectus was given a good many years ago by Noyes as from 5 to 8. He thought when it fell below 5 it indicated a definite weakness of the externus itself; when it was above 5 and less than 8, it indicated a normal external rectus prism power, and over 8, an excessive prism power. I have studied out a good many cases that have been affected by hypermetropic correction. After H refraction is corrected, esophoria has lessened or disappeared entirely, provided the abduction is from 5 to 8 degrees, but it scarcely ever disappears when it is less than that. The explanation of esophoria is that the patient has a defective relative convergence. He cannot separate his convergence from his accommodation; consequently in obtaining vision before his refraction error has been corrected the extra innervation of the ciliary muscle goes also to the internal rectus. Then we have got by the phorometer esophoria, which does not mean external weakness at all, but overaction of the internal recti.

DR. EDWARD JACKSON, Denver: The main fact that stands out from Dr. Zentmayer's study is that for each individual there comes to be established, with approximate permanence, a certain ocular balance; as in each eye finally, in the process of development, a certain relation is established between the length of the anteroposterior axis and the curves of the surfaces. Orthophoria is rare, just as emmetropia is rare, but it is an approximation in that direction. The point is that a relation is established that becomes the fairly permanent condition for that individual. Any person with heterophoria overcomes it by his innervation, and so departs from that permanently established condition of rest. In certain cases there is a more continued departure in the interest of single vision; there may be apparent change in the balance from temporary strain. A patient with presbyopia goes too long without having his glasses changed, and comes to one of us when the near point has gone off to 16 or 20 inches, and he has been straining his accommodation. Frequently in these cases I have found a distinct departure toward esophoria, from the balance I had recorded years before. If the patient, however, gets the correction for the presbyopia and uses it for a few weeks he will come back to the previous state of muscle balance, which may be regarded as the permanent state of balance for that individual. A permanent state of muscle balance is not necessarily congenital, but it is established, perhaps, in rather early childhood, or not entirely until the approach of adult life. I would like to see this subject studied from the point of view of age. My impression is, though I cannot give statistics to support it, that heterophoria is decidedly more influenced in young persons, particularly in young children, by the wearing of corrections for ametropia than it is in adults. I think any such study as Dr. Zentmayer's ought, in future, to consider that, and the cases should be classified according to age. Perhaps that would give us more distinct results.

DR. FRANCIS VALK, New York: Some twenty-five or thirty years ago, at a medical congress in Washington, this subject of esophoria for distance and exophoria for near was discussed, and since that time it has been spoken of in various text-books, but I do not know that any one has explained why we should have homonymous diplopia at 20 feet and crossed diplopia at a shorter distance. I was surprised to hear Dr. Stevenson's report of a patient securing more comfort by holding the book to the right or left. In such cases there must be some tendency for the eyes to turn in a certain direction. I have also noticed that the

text-books, in treating of the rotation of the eye, have decided on a fixed condition of 55 degrees inward and 50 degrees outward. In several cases I have found, in the right eye, a rotation inward of about 45 degrees, and an outward rotation of 55 degrees; in the left eye, 60 degrees inward and only 40 outward. Now if the standard is correct we have here, unquestionably, an exophoria in the right eye taken alone, and esophoria in the left eye taken alone. Now it seems to me reasonable that, when a person looks in the distance, the left eye is esophoric, from the weak outward rotation. In the near the right eye becomes slightly divergent owing to the weak internus and there is exophoria. There is a decided tendency here for both eyes to turn to the right. I think this explains these cases very clearly. All cases of esophoria in the distance and exophoria in the near invariably show this condition. What to do from this point is interesting. We should not put on prisms for distance or for esophoria, nor prisms for exophoria. When esophoria predominates I put a prism over the left eye only base outward and none over the right and it works very successfully. On the other hand, if the exophoria predominates, I put a prism over the right eye with the base in. In some cases I have put the base out over the left eye and base in over the right. These are patients we cannot very well operate on. They do not show a real reason for operating but do show a reason for prisms. Many of you know the term dextrophoria which I have advanced in these cases. My suggestion was not a very good one because it is a combination of Latin and Greek, instead of Greek alone as it ought to be. But the name simply shows the actual tendency of the eyes to rotate in an abnormal condition similar to that of anaphoria.

DR. SAMUEL THEOBALD, Baltimore: One of Dr. Zentmayer's conclusions caused me some surprise; that exophoria for distance and near will be practically unchanged by the correction of compound myopic astigmatism. If the statement had been as to simple myopia I should have unhesitatingly challenged it; but the fact that astigmatism is associated with the myopia is a saving clause. In such circumstances, the effect on the exophoria I should say would depend on whether the myopia was considerable and the astigmatism slight, or the reverse. If the myopia is at all considerable, its correction will surely lessen the exophoria at reading distance. On the other hand, if there is pronounced astigmatism, the relief of the accommodative effect required to overcome this might more than offset the correction of the myopia. With regard to the influence of the correction of anisometropia on the muscle-balance, I have seen some extraordinary results. One case I published in which a marked divergent squint quickly disappeared, under the influence of glasses which equalized the focus of two very dissimilar eyes. Another striking example of the influence of glasses on muscle balance, is shown in cases that Dr. Zentmayer and all of us have seen, cases of convergent squint in which the squint is absent with convex glasses of 3 or 4 diopters but returns at once when the glasses are removed.

DR. GEORGE H. PRICE, Nashville: I am sorry Dr. Zentmayer did not include the testing of the accommodation in the individual prior to the correction of the vision, because on this point, in my opinion, hinges largely the effect which will be produced by the correction of any defect of vision when it is associated with imbalance. Cases in which we have esophoria for distance and exophoria for near and the exophoria increased with lenses, show that if the accommodation is suspended to determine the entire refractive error and a full correcting lens put on without reference to the amount of accommodation the individual had originally, you are apt to meet with the condition that supervenes in the cases reported by Dr. Zentmayer, because you have an overcorrection of the hypertropic condition. This will be a great inconvenience to the patient when he begins to wear the glasses, and if you make a test within a few weeks before the eyes have become adjusted to the new condition, the patient will show a different disturbance in the muscle balance from the original. Put on a correcting lens of a diopter or more and you have relieved the patient of

the necessity of making that much effort at accommodation and the patient feels the lack and the muscle balance sympathizes with it and is disturbed temporarily. Esophoria for distance and near both were reduced; at times exophoria for distance manifested itself after the correction was on. If both are reduced then in the majority of cases you have the proper correction, but if you have carried your correction too far and you take away from the eye the original impulse to which it was accustomed for a long period of time, to bring about the necessary convergence it lags, because it does not get the proper stimulation, then you have a little bit of exophoria.

DR. WILLIAM H. BATES, New York: I take issue with every conclusion that has been made. I believe most of us recognize that myopia is acquired. We have seen cases of astigmatism acquired. Some of them get better and some get worse. Dr. Zentmayer reported that heterophoria changed. I have also observed changes occur in errors of refraction. I believe that the cause of many cases of heterophoria, myopia and astigmatism is psychic. To illustrate: A boy came to me with 4 or 5 diopters of mixed astigmatism under atropin. He never had been able to read more than a few minutes at a time and then only with much headache and pain. His mother (by a method of eye-training which I published) cured his defective sight for distance. Later, after some months without glasses, he became able to read Jaeger No. 1 without any asthenopia, without any apparent exophoria or esophoria and I believe that the cause of the heterophoria and the astigmatism in that boy was psychic.

DR. OTIS ORENDORFF, Canon City, Colo.: From a practical point of view we should consider diseases of the nasal cavity and associated sinuses. But little reference has been made to them. If you will make careful investigation of some of the most perplexing cases with associated phorias you will find numerous cases of nasal disease, and when they are cleared up the phorias will be also cleared up, and you will never be able to do it while the disease exists in the nasal cavities.

DR. MARK D. STEVENSON, Akron, Ohio: A point of interest found by the essayist is that right is more frequent than left hyperphoria. There are many possibilities entering into the explanation of this. It occurs to me that the most likely cause comes in line with what Dr. Jackson has just suggested. Just as good habits in children may assist in correcting deformities, so evil habits of looking may bring about undesirable changes. In a child at a desk sitting in a half-turned position, reading may produce hyperphoria. The difference in the distance between each eye and the reading matter is probably not very important; but the difference in the use and, therefore, in the development of the muscles is likely of great importance and has a real physical basis. For example, in looking much of the time down and to the left, the chief depressor of the right eye is the right superior oblique, and of the left, the left inferior rectus. Therefore, physically, the left inferior rectus will be more developed than the right and in looking at the distance where the muscle balance is usually tested, if desire for fusion is abolished, the more developed muscle will probably exert the greatest influence; and in this case turn the left eye lower which would explain the greater frequency of right hyperphoria. In testing such a patient's hyperphoria when looking to the left, left hyperphoria according to this theory would likely occur on account of the overaction of the hypertrophied right superior oblique. Left hyperphoria could also be explained on the same theory as the causation in those who habitually look downward and to the right. These habits will often vary with the individual and school. As fusion is abolished in the tests, this physical theory seems more plausible than differences in innervation.

DR. WILLIAM ZENTMAYER, Philadelphia: I feel the weakness of the paper. If I had it to do over again, I would ask advice from many confrères, as I did of some in Philadelphia, as to what I should look for and how to go about the analysis. I think one of the points Dr. Jackson made is very strong, that it would have been well to have studied the cases also from the point of age. In a discussion of this

kind much that comes out is based on what I wanted to overcome by my paper. We all have ideas as to the ratio and relations of things, but when we come to analyze our cases we find our preconceived notions were wrong many times. I think some of the discussion proceeds along the line of the notions we have had. Replying to Dr. Valk I would say that last year we had a paper by a member of this Section in which it was declared that, in cases showing esophoria for distance and exophoria for near, the esophoria was a pseudoesophoria due to spasm from excessive effort at convergence to overcome the weak convergence. My cases do not bear out that view. With regard to presbyopia, as Dr. Jackson said, these cases, in time, right themselves, but I think it is better to follow Dr. Stevenson's suggestion and stimulate the convergence by putting on the weakest glass with which the patient can get along. The normal balance is also restored more quickly by prism exercises when the correction of the presbyopia has disturbed the relation between the convergence and the accommodation. As to Dr. Davis's exception to my conclusion that, on the whole, the heterophoria is not greatly influenced by the correction of the ametropia, I would say that perhaps we differ only as to our interpretation of the word "greatly."

Dr. Theobald has spoken of compound myopic astigmatism and the exophoria disappearing under its correction. Had I grouped the cases as to time—months and years—the results might have been different. I think that, probably, is the reason for the total average result being somewhat different from what might be expected from the correction of compound myopic astigmatism.

FUNCTIONAL HEART-BLOCK IN PNEUMONIA

SELIAN NEUHOF, M.D.

Visiting Physician, Har Moriah Hospital; Adjunct Attending Physician, Lebanon Hospital

NEW YORK

CASE 1.—N. R., man, aged 70, entered the German Hospital in a semicomatose condition. The only previous history, with any bearing on his present complaint was that he had been ill for several months prior to admission; but neither the nature nor the symptoms of this illness could be determined. On examination he had marked paralysis agitans. The pulse-rate was 36 per minute and regular. The pupils reacted normally to light; the knee-reflexes were absent. There were signs of diffuse bronchitis with suspected areas of consolidation in both lungs; tubercle bacilli were not found in the sputum. The cardiac area appeared normal to percussion; the heart-sounds were indistinct; no murmurs were heard. Abdominal examination revealed nothing abnormal. The radial arteries felt somewhat thickened. There was no edema of the legs. Cheyne-Stokes breathing was absent. The patient was slightly dyspneic and cyanotic and gradually lapsed into complete coma. The pulse remained slow and regular throughout the illness, its rate varied between 34 and 36 per minute. The temperature ranged between 100 and 103 F.; on the day of death, one week after admission, it rose to 105.

Polygraphic tracings were obtained on different days; on one occasion, the radial pulse was 35 and the auricular rate 102 per minute (Fig. 2). There was no numerical ratio between auricular and ventricular contractions, the auricular waves (*a* waves) fell before, immediately after or with the carotid beats (*c* waves); in other words, complete auriculo-ventricular dissociation (complete heart-block) existed. The subcutaneous injection of 1/50 grain of atropin sulphate had no effect on the block (Fig. 3). For purposes of comparison, a normal tracing is shown (Fig. 1) with a normal pulse-rate and the rhythmic progression of *a-c-v* waves in the jugular pulse.

The following notes were abstracted from the post-mortem findings: The brain was slightly congested; its membranes

were normal. On gross section, the spinal cord appeared normal. There were several areas of pneumonic consolidation and evidences of general bronchitis. The gastro-intestinal canal, liver and pancreas were normal. The spleen was somewhat enlarged and congested. The renal capsules were slightly adherent; the organs themselves were congested and showed slight evidences of chronic interstitial changes. There was no lesion of the auriculoventricular bundle,* though it contained a little more connective tissue than is usually found. There was a slight amount of fatty infiltration of the auriculonodal junction, but its dimensions were sufficiently large to carry impulses. There were some moderately large areas of sclerosis in the interventricular septum, but these did not interfere with the continuity of the bundle.

CASE 2.—J. C., man, aged 49, entered the Lebanon Hospital with the typical history of acute pneumonic invasion: One week before admission he had had a severe chill; a day later fever, cough and rusty expectoration developed. On admission, the rectal temperature was 104; there was consolidation of the upper lobe of the left lung; the cardiac area could not be mapped out by percussion; the heart-sounds were distant and scarcely audible; the radial pulse was 120, regular and felt small; the blood-pressure (auscultatory method) was 100 mm. systolic and 60, diastolic. The patient was extremely collapsed and slightly stuporous. On one occasion the urine contained a heavy trace of albumin but no casts. For one week the temperature ranged between 101 and 104; the pulse remained regular. Its rate varied between 108 and 140 per minute, the systolic blood-pressure between 100 and 78 mm., the diastolic between 60 and 0 mm. The temperature then dropped by crisis to 97.5 by rectum. The pulse-rate fell to 88 and was regular. On the ninth day after admission, the ventricular rate suddenly fell to 44 per minute and for four days varied between that and 30. The patient remained in extreme collapse and semistupor with a rectal temperature below 98. The pneumonic area gradually underwent resolution, the radial pulse was very small, there were no visible jugular or carotid pulsations, and the heart-sounds were scarcely audible. There were no general convulsions, but there were frequent attacks of convulsive tremors of the musculature of the upper and lower extremities, which became very cold and cyanosed; the pulse then became very slow and scarcely perceptible and the semistupor changed to deep coma. Each attack lasted about one minute. Two days later the average pulse-rate was 48; the general condition remained the same.

Suddenly on the sixteenth day after admission and one week after the inception of the slow rhythm, there was a marked change in the patient's condition; he sat up in bed, was fully oriented, his color was good, the ventricular rate was 76 per minute and regular, and the heart-sounds though still faint, could be readily heard. There was a soft systolic murmur at the apex. Except on three different occasions, when the pulse-rate fell for a short time to 48, 44 and 40, the rate varied between 60 and 80 and remained regular. Polygraphic tracings were attempted during the period of slow rhythm but were unsatisfactory apparently because of the collapsed arterial and venous circulation. Two weeks later, electrocardiograms which I took showed sequential contractions uninfluenced by pressure on either vagus. The heart-sounds were then normal, the systolic blood-pressure 120 mm., the diastolic 70 mm. Prior to the inception of the slow pulse, 1 ounce each of digalen and the tincture of digitalis had been administered. There was no vomiting throughout the illness.

COMMENT

In Case 1 the history was too meager to approximate the duration of the heart-block prior to the patient's admission to the hospital. From the absence of any organic cause for heart-block in the pathologic examination it is reasonable to assume that pneumonia was the exciting cause of the block. In Case 2, the sudden

drop of pulse-rate and its continued retardation for one week, the frequent slight muscular tremors, the general and circulatory collapse and the sudden resumption of normal pulse-rate leave no doubt as to the presence of heart-block. In the absence of graphic tracings, its nature—complete or incomplete—could not be determined. Since digitalis preparations in large amounts had been given previous to the onset of the block, its action as a possible cause for the latter requires consideration. It has been part of our routine in the treatment of pneumonia to give digitalis preparations by mouth or hypodermically in amounts similar to those administered in this case, but they never reduced the pulse-rate. It is well known that digitalis may produce heart-block. I have seen several cases of endocarditis with broken compensation in which digitalis produced block, but it was not accompanied by collapsed circulation; in fact, decompensation often improved; vomiting usually accompanied the digitalis poisoning. Mackenzie¹ reports a case of cardiac decompensation in which digitalis produced partial heart-block, extrasystoles and alternation; the drug was pushed until the patient vomited; he was very much improved despite these arrhythmias. In my case there was no vomiting; the block came with the crisis; the patient was collapsed and there were slight convulsive tremors. These symptoms continued for one week after digitalis was stopped, and the sudden resumption of normal pulse-rapidity was accompanied by marked beneficial changes in the patient's sensorium and appearance. None of these symptoms resembles digitalis heart-block. It thus appears most probable that though the digitalis may have been a factor in the production of the block, its main cause was the pneumonia.

A sudden drop of pulse-rate to 60 or even 50 per minute with regular ventricular action is not infrequent in pneumonic crises, but such slow rhythms have not been sufficiently studied by graphic methods to determine whether they are true bradycardias (slow sequential auricular and ventricular beats) or are possibly due to heart-block. Hecht² reports a case of influenza in a child in which the electrocardiograms showed heart-block, which still persisted several months after convalescence. Magnus-Alsleben³ reports a case of pneumonia in which digitalis had been given; the temperature fell by lysis; polygraphic tracings apparently show that every third or fourth ventricular beat is blocked. Bachmann⁴ has tabulated all the cases of heart-block reported up to 1912; pneumonia is not mentioned as a causative factor. Mackenzie⁵ states that the invading organism may assail the heart as well as the respiratory tract. Organic changes such as lymphocytic or leukocytic infiltration in or near the junctional tissues, marked myocarditis or cardiac infarct can be excluded, in Case 1 by the pathologic examination, in Case 2 by the sudden inception and relief from block and the other data given.

I have not been able to find any reports in the literature in which pneumonia was accompanied by heart-block with slow ventricular action and with no organic discoverable cause. There is ample evidence that heart-block may exist without any recognizable pathologic change in the cardiac structures; thus, Lewis and

* I am indebted for the report of the examination of serial sections of the heart to Dr. A. E. Cohn of the Hospital of the Rockefeller Institute for Medical Research.

Mathison⁶ produced it by asphyxia, and Buchanan⁷ showed that it is a physiologic phenomenon in hibernating animals. One may conceive several methods by which a chemical poison like the toxin of pneumonia circulating in the body may produce heart-block: thus, first, by a central effect on the cardio-inhibitory centers in the medulla; second, by profound disturbance of the nutrition or circulation of the general cardiac musculature or its auriculoventricular connections, or third, by an effect on the peripheral intracardiac ganglia and nerves. Our present knowledge of the last is so vague that its discussion would be fruitless. Regarding the first hypothesis, Einthoven⁸ produced varying grades of complete and incomplete block in dogs by morphin injection and conceived it as due to the effect of the drug on the vagus centers in the medulla. In pneumonia the primary danger of circulatory failure is also probably due to central depression of the vasomotor system.⁹ Cardiac failure in the ordinary sense was absent in my cases, there was very slight or no dyspnea, and edema was absent. Though it is impossible to exclude the effect of the toxins on the general and specific cardiac musculature (the second hypothesis) as a causative factor of the block, the symptoms and the dissociation were probably due to toxic depression

Fig. 1.—Normal polygraphic tracing. Rhythmic progression of a-c-v waves is seen in the venous tracing.

Fig. 2.—Complete heart-block. The auricular beats (a waves) have no sequential relationship to the carotid beats (c waves); they fall before, after or with the carotid beats.

Fig. 3.—Tracing taken after the injection of atropin sulphate, 1/50 grain. Complete heart-block is still present.

In the tracings r=radial beats, a=auricular waves, c=carotid waves. The time-marker indicates 1/5 seconds.

of the cerebral centers and not to any direct action on the heart.

The injection of atropin sulphate in Case 1 did not raise the block. It is usually assumed that the disappearance of arrhythmias after atropin injection is an evidence of their functional nature. The contrary, however, is not true, for other factors, such as drug idiosyncrasies and the continued presence of counteracting poisons (toxins) may prevent or retard the disappearance of functional arrhythmias following atropin injections.

SUMMARY AND CONCLUSIONS

Two cases of heart-block occurring in pneumonia have been described. In the patient who died, the pathologic examination showed no cause for block. Both cases were probably produced by pneumonic toxins which acted on the medullary centers. The

injection of atropin sulphate in Case 1 had no effect on the block.

I am indebted to Dr. J. Kaufmann, attending physician, German Hospital, and to Dr. R. Stein, attending physician, Lebanon Hospital, for the privilege of reporting Cases 1 and 2, respectively; also to Dr. F. B. Humphreys, pathologist, German Hospital, for the post-mortem notes of Case 1.

THE TOXICITY OF CAMPHOR (CAMPHORATED OIL)

D. J. MILTON MILLER, M.D., ATLANTIC CITY, N. J.

In his "Therapeutics" (edition of 1906), H. C. Wood makes the following statement: "Although camphor has, in many cases, produced very alarming symptoms, over 200 grains of it have been taken without permanent result and the recorded fatal poisonings are very few. The only ones known to us are,—adult, quantity unknown; sickly infant, 10 grains; child, 2 years old, quantity unknown; fatal abortion produced by 3 drachms."

On the evening of June 3, M. C., a particularly robust infant of 18 months, weighing 31 pounds, was given, immediately after a full supper of milk and cereal, a brimming teaspoonful of camphorated oil (linimentum camphorae) by mistake. Two hours later I saw the child. It was sleeping quietly and naturally, with cheeks somewhat flushed and the scalp quite wet with perspiration, not an unusual phenomenon with it; the pulse was 110, the respiration 24. When awakened, the infant was found to be quite natural, playing and smiling in its usual manner, and, as nothing abnormal was discovered, nothing was done beyond the administration of 2 drams of castor oil. The child was then replaced in its crib, but was very restless, not falling into a sound sleep until near midnight, a condition which could be attributed as well to its having been disturbed as to the overdose of camphor. The infant awoke the next morning perfectly well, apparently quite unharmed by its unwonted medication.

As camphorated oil is a 20 per cent. solution of camphor in oil, the dose of camphor, given this infant of 18 months, must have been from 14 to 15 grains, the mother having given a brimming teaspoonful (from 1.25 to 1.33 drams); yet there were practically no symptoms.

127 South Illinois Avenue.

Rapid, Painless, Bloodless Method for Removing the Inferior Turbinate.—Nothing especially novel or original is claimed for this operation. It is reported only because of the ease and rapidity with which it is performed and the freedom from adhesions afterward. The primary requisite is an extra long Curtiss nasal trephine (1½ by ¼ inch), a pair of cutting forceps and an elevator for the mucous membrane. The nose is thoroughly anesthetized with crystals of cocain and a 1:1,000 solution of epinephrin. The mucous membrane having been lifted up with elevator over the lower turbinate and all adhesions having been removed, the bone is drilled through lengthwise with the trephine and all projecting edges are removed with cutting forceps. A Bernays compressed sponge which has been first wrapped with paraffin-paper and the ends left exposed is inserted into the nose. The paraffin-paper prevents the sponge from adhering to the wall of the nose, sufficient moisture having been absorbed through the uncovered ends to permit of swelling and at the same time prevents too much pressure on the inflamed surfaces. After three days this tampon is removed. It will be found to be free from blood and at no time either before or after the introduction of the tampon will there be enough blood to discolor a paper napkin. A simple oil spray is ordered and as primary union takes place and as the nasal fossae are widely patulous, no adhesions form.—W. PEYRE PORCHER, M.D., Charleston, S. C.

THE ACTUAL ACIDITY OF HUMAN GASTRIC JUICE

To anyone whose physiologic ideas are rooted in dogmatic or inherited statements it will seem bold to question one of the most wide-spread, sanctioned beliefs of clinical medicine. There is an assertion current in every treatise bearing on the stomach and its disorders that the human gastric juice normally contains about 0.2 per cent. of hydrochloric acid. That the gastric secretion of laboratory animals, the dog for instance, may show a decidedly greater acidity, commonly exceeding 0.5 per cent. of hydrochloric acid, is well appreciated. This discrepancy between the species has frequently received comment and been explained on teleologic grounds. Few persons have stopped to consider that in recent years the gastric juice procured for analysis from dogs has usually been obtained pure, directly through a fistula made for the purpose; whereas the figure accepted by both physiologists and clinicians for the secretion percentage in man was arrived at by examining the contents of the stomach, and not the uncontaminated juice. The bearing of this will appear presently.

There have been suspicions, from time to time, that the accepted figures for the "normal" gastric juice were involved in some uncertainty. The doubts have arisen as a rule among the gastro-enterologists who have occasion daily to decide as to the existence or absence in patients of hyperacidity or hyperchlorhydria. Most of the influential writers have stated that any amount of hydrochloric acid above 0.2 per cent. is to be considered a hyperacidity. On the other hand, cases are repeatedly encountered in which a greater acidity than this figure gives rise to no symptoms of hyperacidity. The situation is complicated by the fact that subjective elements enter into the judgment of the normality or abnormality of the features presented by the human patient. According to competent clinicians, symptoms of hyperacidity may exist even in cases of hypo-acidity. Consequently, those physicians who are willing to disregard the dictates of inflexible rules in diagnosis conclude that the same

amount of acid may indicate a hyperacidity in one person and not in another, showing that individual variations may exist in the so-called normal percentage, and that a sharp line of demarcation cannot always be drawn between the normal and the hyperacid state. This has compelled critical clinicians to refer the symptoms of what is called hyperacidity to a hypersensitiveness of the gastric mucosa toward certain strengths of hydrochloric acid. Ulceration, erosion, atony and sensory neurosis may be factors which serve to correlate certain chemical findings with the sensory disturbances.

Pawlow of St. Petersburg, whose classic researches on the digestive glands won for him one of the early Nobel prizes in medicine, long ago came to the conclusion, on the basis of numerous researches on the pure gastric juice of dogs, that its acidity is essentially constant. The volumes produced may vary widely; not, however, the concentration of hydrochloric acid. There are fluctuations in the course of successive hours and in connection with different types of stimuli, which Pawlow explained as follows: The fluid secreted by the glands proper, which he terms "native" juice, always has a definite acidity. In pouring over the mucous membrane of the stomach this highly acid native juice undergoes a partial neutralization by the alkaline mucus. For this reason juice collected from a fistula may show a somewhat lower acidity during the early period of collection than later. The acidity of the juice actually removed for examination will accordingly depend on the relation of the secretion to the production of gastric mucus and also on the rate of flow. If gastric juice remains for any extended period within the stomach it likewise experiences considerable neutralization. Pawlow argued that in man the native acidity of the secretion of the gastric glands could not differ very much from the high figures (from 0.5 to 0.6 per cent. hydrochloric acid) noted for dogs and cats; and that it must always be constant, because man's food and the construction of his digestive organs are very similar to those of the animals mentioned. Clinicians, however, were not of this opinion.

In recent years, through conditions of accident or disease, a large number of gastric fistulas in human beings have made it easier to obtain pure gastric juice from man. The percentage of hydrochloric acid noted by various observers is sufficiently interesting and significant to be recorded here: Umber (1905), 0.35; Pfaundler (1900), 0.35; Hornberg (1904), 0.48; Goorevitch (1903), 0.37; Moritz (1901), 0.38; Seiler (1901), from 0.32 to 0.44; Verhaegen (1898), 0.48; Sommerfeld (1905), from 0.38 to 0.47; Carlson (1912), from 0.43 to 0.48.

Shall we explain these concordantly high figures obtained in widely separated parts of the world under unlike conditions as consistently due to hyperacidity?

Boldyreff of Kasan, Russia, an investigator favorably known for his contributions to the physiology of digestion, has offered an explanation to reconcile the seemingly contradictory facts in this field.¹ It has been difficult to explain why juice obtained from the entire normal stomach as distinguished from that obtained from experimentally isolated portions of that organ should almost always contain a lower concentration of acid, namely, from 0.1 to 0.2 per cent. of hydrochloric acid, the figures previously quoted. The key, in Boldyreff's judgment, is the observation made by many scientific workers, that the acidity of various acid fluids is reduced during their stay in the stomach. If the stomach always has, for some reason, a tendency to reduce to a definite average the acidity of foreign acid fluids brought into it, it is natural to suppose that either when empty or in those cases in which food material entering it is not capable of such reduction, the stomach similarly reduces the acid juice secreted by its own glands.

Opinion has been divided concerning the mechanism by which the acidity in the stomach is reduced; some attribute it all to the alkaline mucus secreted by the mucous cells of the interior surface of the stomach, others to the pyloric juice, and others to a special secretion supposed to serve the sole purpose of dilution. The saliva and mucus are doubtless minor agents in the partial neutralization of gastric acidity. Boldyreff considers the principal factor concerned to be the pancreatic juice, the strongest alkaline fluid in the body. It has long been known to neutralize the acidity of that portion of the intestinal contents which is next to the stomach; and we are now told that it fulfils the same function within the stomach.

The theses set up by Boldyreff may be summarized as follows:

The acidity of freshly secreted gastric juice is constant (0.5 per cent. hydrochloric acid). This is rapidly lowered to a level which oscillates between 0.15 and 0.2 per cent. The same thing happens after the introduction of any acids foreign to the stomach. This partial neutralization is due to the reflux into the stomach of alkaline juices from the duodenum, the pancreatic juice being here the most important factor. Neutral, alkaline, or feebly acid fluids provoke a secretion of the acid juice in order that the acidity may be brought to the normal level. The mechanism described for maintaining the optimum level of acidity—from 0.15 to 0.2 per cent.—is designated by Boldyreff as the "self-regulation of the acidity of the contents of the stomach." In cases of chronic absence of the pancreatic juice or an insufficient influx thereof into the stomach there is an accommodation whereby the scarcity is made up by an abun-

dant influx of bile and intestinal secretion into the stomach.²

Though it is thus easy to reconcile the divergent results obtained, on the one hand, by clinicians working with gastric contents, and, on the other, by physiologists examining the pure secretion, it is nevertheless not necessary to deny the existence of such a pathologic condition as hyperacidity. All the factors involved should be considered, however, before making a diagnosis. The gastric juice may be perfectly normal and yet show a high acidity, because sufficient time has not elapsed to allow the regulatory partial neutralization to occur; there may be delay in the entrance of intestinal secretions into the stomach, or these may not possess the usual requisite alkalinity. We must seriously consider, therefore, whether the condition described by clinical observers as hyperacidity is not sometimes the expression of a lack of the most important neutralizing fluid, the pancreatic secretion, rather than a pathologic state of the gastric juice. The abnormality can actually be produced in animals by ligating the pancreatic ducts.

A high initial acidity of the gastric juice is advantageous for the destruction of bacteria which find their way into the upper digestive tract. The reduction to a lower degree of acidity has subsequent advantages, among which, obviously, is the prevention of injury to the small intestine. It is another story of wonderful regulatory mechanisms.

THE NUTRIENT VALUE OF INORGANIC SALTS OF LIME AND PHOSPHORIC ACID

The reluctance to admit the nutrient value of some of the inorganic compounds of elements like iron, calcium and phosphorus as compared with "organic" preparations is gradually being overcome. This preference for organic compounds is, we presume, a surviving expression of the old belief that there is an exceptional virtue in products which resemble in some degree the components of the living body. In its earliest phases this view was emphasized by the assumption that a diet of meat was particularly well adapted to the building of muscle; and similarly "organic" iron preparations were somehow looked on as preferable for "blood-building." To-day new experimental research is no longer required to justify the contention that "organic" and inorganic iron are alike available. This conclusion, so firmly fortified by elaborate investigation a decade or more ago, is quite in harmony with the modern studies on the chemical changes taking place in the alimentary tract. There is little doubt that whatever the combination in which they are ingested, iron and calcium and phosphoric acid are in good degree "ionized" by the digestive

processes; so that even the "organic" preparations in truth result in inorganic derivatives before they are ready for absorption.

Although the problem here set forth is in a sense settled for iron, the utilization of inorganic compounds of lime and phosphoric acid has not been so readily admitted in practice. Experiments on animals demonstrating the conversion of ingested inorganic phosphates into characteristic phosphorized tissue products, like the eggs of birds or the milk of mammals, for example, have not been lacking. But as usual it has been the demonstration of the fact on man that was needed to bring final conviction.

Accordingly, we may welcome the evidence now submitted from the Grossen Friedrichs-Waisenhaus of Berlin by Drs. Schloss and Frank¹ respecting the availability of tricalcic phosphate for the development of bone in growing infants. Elaborate balance experiments on children have shown convincingly the improved retention, not only of the elements represented in this inorganic compound, but also of other metabolic factors such as nitrogen and alkalies in addition, after this inorganic phosphate has been administered in the diet. The improved utilization following the use of tricalcic phosphate was not merely transitory; the advantage accruing therefrom was maintained. We may conclude, therefore, that even in the organism of the growing child so simple a compound as an inorganic salt of calcium can easily be absorbed and advantageously assimilated.

THE AIR OF RAILWAY TUNNELS

The discomfort of travel through smoke-filled railway tunnels is well known, but the question as to the possible effect of the gaseous impurities on the public health has not received the attention which it deserves. The result of such a study has just been published by the Hygienic Laboratory of the United States Public Health Service.² The relative amounts of sulphur dioxide and of carbon monoxide found under ordinary conditions in a typical non-electrified and a typical electrified tunnel (those of the Pennsylvania and the Baltimore and Ohio Railroads at Baltimore) were accurately determined. The results show that on an average there was about five times as much of the two gases in the tunnel through which coal-burning locomotives pass as in the one through which the trains are drawn by electric tractors. It was shown that the amounts of the gases in the non-electrified tunnel are subject to great variations, depending on traffic conditions. The probabilities are that a person will encounter noticeable amounts of sulphur dioxide in four cases out of five and disagreeable or very irritating amounts in two out of every five trips.

The amounts of sulphur dioxide found in the non-electrified tunnel varied from 0.6 to 15.1 parts per million, and the corresponding figures for the electrified tunnel were from 0.3 to 2.9 parts per million. In the case of carbon monoxide the amounts in the non-electrified tunnel varied from 4 to 267 parts per million, and for the electrified tunnel, from 3 to 25 parts per million. In order to ascertain what effects these quantities might have on passengers passing through the tunnels, Seidell and Meserve² reviewed the literature of studies which have so far been made of the action of these gases on animal organisms. It was found that results on minute amounts of the gases are quite meager and the statements concerning their action are in very general terms, so that no really satisfactory idea of the maximum amounts which can be tolerated without injury can be obtained. The question is naturally one which does not lend itself readily to solution. Individual variations and idiosyncrasies will play an important part in any studies which can be made, and interpretation of the results will vary with the point of view of the interested person.

The principal value of the data contained in the bulletin of Seidell and Meserve is to show the actual amounts of the gases present and the reduction in the amounts which can be accomplished through electrification. The question as to whether or not the quantities present are dangerous to health, can be answered only on the basis of extensive physiologic experiments made with similar quantities of the gases. In regard to the discomforts of travel through smoke-filled tunnels there is no question. It does not appear possible at present, however, to affirm that the gaseous impurities in non-electrified railway tunnels are a menace to the public health and therefore justify a demand that the conditions be ameliorated. It seems likely that persons suffering from respiratory or circulatory disturbances may have the condition aggravated by passage through tunnels containing coal-gases, especially sulphur dioxide.

CONGESTIVE AND OTHER CONDITIONS OF MENSTRUATION

The menstrual period has long been regarded as inevitably bringing pain or discomfort and more or less disability to a large number of women at frequent intervals. Experimental investigation relative to menstruation has been largely impossible, so that at best the conclusions on this subject have been based on statistics of various sorts gathered from diverse sources. Comparable functions in the lower animals afford few facts bearing directly on menstrual phenomena noted in the human species. To the minds of those who give attention to the physical degeneration and suffering of an increasing number of women, the question invariably suggests itself, however, whether

2. Seidell, Atherton, and Meserve, Philip W.: Gaseous Impurities in the Air of Railway Tunnels, *Hvg. Lab. Bull.* 92, U. S. P. H. S.

modern conditions of living or dress—factors of personal hygiene—are not responsible for a considerable share of the real or imagined difficulties that have been encountered. Like many other physiologic problems, that of menstruation and its attendant symptoms is so bound up with traditions, inherited prejudices and uncritical personal judgments that the open-minded reviewer is often checked in his attempts to untangle fact from fancy.

Quite recently two contributions¹ have been recorded which should help to eradicate the belief in the inevitable "illness" as the dominating characteristic of menstruation. Dr. Mosher believes that many of the untoward features of functional dysmenorrhea are due to remediable conditions. The periodic physiologic congestion which occurs about the time of menstruation is frequently so excessive that it produces congestive dysmenorrhea. The upright position, lax abdominal muscles, costal instead of diaphragmatic breathing and constriction of the body by clothing which interferes with the use of the diaphragm and abdominal muscles—all combine to develop and promote the excessive pelvic congestion. As a result of such conditions, rather than of any inherent natural organic changes, there may be pain at the menstrual period, prolonged hemorrhage and undue loss of blood. These consequences, Dr. Mosher believes, may be averted by suitable physical therapy.

Despite the widely accepted belief that menstrual disability among women is inevitable, Dr. Mosher insists that under normal conditions there should be no more suffering with disorders of the generative organs than with disturbances of the digestion. She concludes that at present all the evidence points to the menstrual hemorrhage as a secondary matter more or less fixed by the upright position. It is unnecessary and undesirable that it should be of more than brief duration or of more than slight amount. Pain and discomfort, where no organic lesion exists, are readily controllable by the physiologic regulation of the circulation from the abdomen and pelvis back to the heart, by the restoration of the tone and action of the diaphragmatic and abdominal muscles. This is accomplished by suitable bodily exercises. Other coincident functional disturbances, such as congestive headaches, are simultaneously relieved by the "equalizing" of the circulation.

Dr. King has searched with little success for the evidences of rhythm in the organic activities which has so long been emphasized by writers on the subject. Granted that a lowering in pulse-rate, temperature and blood-pressure occur during the menstrual and post-menstrual periods, she asks if much signifi-

cance should, after all, be attached to a diminution in pulse-rate of from two to three beats, to temperature variations rarely greater than 1 degree, and to blood-pressure changes averaging from 2 to 5 mm. Certainly, Dr. King adds, one would suppose that in a healthy individual a normal periodic function should not be accompanied by marked depression of all the life-processes and the generally lowered efficiency so emphasized by numerous writers. If there is a compensation for the loss of blood, it would seem that there should be a compensation in the cardiovascular system. Perhaps this is indicated in the tendency of the blood-pressure to show such slight variations. It has been remarked with regard to menstruation that we have too long confused cause and effect: the menstrual hemorrhage is not the cause of the alleged blood-pressure rhythm, but an exaggerated result of interference with normal circulation. It is generally believed that primitive and savage women have a very scanty menstrual flow. If we may trust the recent contributions on the subject, it would appear that there has been a tendency to overemphasize the inefficiency of women during the menstrual period.

PHYSIOLOGIC SALINE SOLUTIONS

There are numerous occasions in the routine of clinical practice which may call for the use of saline solutions that shall conserve as perfectly as possible the functional or physiologic integrity of the organs and tissue with which they come into contact. The intravenous or subcutaneous infusion of saline may be cited as an instance of this character. Science has learned long since not only that pure water is actually damaging, not to say indifferent, toward living cells, but also that the older so-called physiologic saline, that is, 0.9 per cent. sodium chlorid solution, is not an ideal fluid for contact with tissues. The salts of various elements or ions, such as sodium, potassium, calcium and magnesium, though used in solutions of suitable osmotic pressure, may still individually be decidedly harmful, the toxicity or detrimental character varying with the individual elements involved. On the other hand, the presence of a little of some ion, like calcium, may overcome the harmfulness of another, like sodium.

To Jacques Loeb, who has devoted much energy and so many years of study to the problems here concerned, we owe the conception of a "physiologically balanced" solution. By this is meant one containing salts of such character and in such proportions that any toxicity which the individual components might exhibit by themselves, if they alone were present in solution, is completely compensated and made to disappear. Loeb has emphasized the antagonism of sodium toward potassium and calcium. The underlying facts here involved were incorporated years ago

by Ringer in the experiments which gave rise to the perfusion fluid bearing his name. Ringer's solution, as is well known, contains a mixture of the chlorids of sodium, potassium and calcium in the proportions of about 0.9, 0.042 and 0.024 per cent., respectively. The details of its composition have been varied by subsequent experimenters in minor respects, by alterations in the relative content of these original components or by further additions, such as alkali carbonate or phosphate. One of the most recent representatives, Tyrode's solution, in which active tissues retain their vitality very well, has the following combination of inorganic ingredients: sodium chlorid, 0.8 per cent.; potassium chlorid, 0.02; calcium chlorid, 0.02; magnesium chlorid, 0.01; sodium phosphate, 0.005; sodium bicarbonate, 0.1.

The test objects which have been employed to ascertain the suitability of the large number of types of "physiologic solutions" have been almost as numerous as the investigators who have dealt with them. Isolated tissue-cells, egg-cells, individual organs like the heart, etc., have served in this capacity. Probably no more sensitive mechanism is to be found than the central nervous system, which speedily loses its irritability and characteristic ability to respond when the fluid medium in which it is bathed fails to suit its needs. For this reason special interest attaches to all investigations conducted with perfusion fluids on the nervous tissues. An unexpected outcome of a very recent study in this field has been the apparent demonstration that the salts of sodium and calcium by themselves provide adequate conditions for the survival of the central nervous system of mammals.¹ According to Gerlach, who developed these facts in Winterstein's physiologic laboratory at Rostock, even minute additions of potassium are objectionable. Calcium and sodium cannot be replaced by other ions. Lithium, for example, was tested in place of the alkali sodium; and the calcium could not be substituted by the related alkali earths barium, strontium or magnesium. Incidentally, the use of calcium-containing solutions in perfusion trials has been observed to prevent or diminish entirely the objectionable formation of tissue edemas, in accord with the contentions of certain physiologists.²

The solution which Gerlach has found most satisfactory for the perfusion of the isolated central nervous system contains 0.9 per cent. sodium chlorid and about 0.05 per cent. dry calcium chlorid. Whether it will prove as suitable for use in human practice as are the "physiologic salines" made up according to current directions, remains to be determined in future experiments. In point of simplicity the new solution

commends itself as worthy of investigation. It may well be that the individual organs—brain, heart, muscles, etc.—differ somewhat in the answer they give to the question of a suitable perfusion fluid. What the clinician primarily seeks is an ideal fluid for infusion into the circulation of the entire body.

MAGNESIUM SALTS, ETHER AND CHLOROFORM

Although the narcotic phenomena produced by the injection of magnesium salts—a procedure introduced by Meltzer and Auer—are now quite familiar, the theories with respect to their behavior have not been in entire accord. It has been noted in animals without exception that a certain dose of magnesium sulphate or magnesium chlorid will produce a deep, often long-lasting anesthesia with complete relaxation of all the voluntary muscles and abolition of some of the more important reflexes. Recovery from such anesthesia is perfect. A larger dose of magnesium salt will produce profound anesthesia and a general paralysis, which, without any preceding or accompanying symptoms of excitation, lead sooner or later to death. The salt invariably effects reduction of excitation or its complete temporary or permanent abolition.

The question has been raised whether or not the symptoms observed represent a true narcosis of central origin or merely a profound paralysis involving the peripheral nervous system. It seems obvious from the fundamental experiments of Meltzer and Auer that complete anesthesia and inhibition of the higher motor centers can be induced by suitable dosage before untoward effects on respiration are evinced. As an indication that the predominant influence is exerted on the central nervous system, Meltzer and Auer showed that, when combined, each in a dose insufficient by itself to produce anesthesia, magnesium salts and ether could initiate that condition without any evidence of peripheral paralysis.¹ The magnesium salt thus appears to supplement the action of a substance which is believed to act on the higher nervous centers. The method involved has been employed successfully in human surgery.²

The problem has been attacked in other ways, one of which is by the use of antagonistic drugs the mode of action of which is precisely known. Camphor, for example, can overcome the effects of agents like paraldehyd or chloral hydrate, which depress the central nervous system; physostigmin antagonizes comparable effects on the peripheral mechanisms. The study of the specific influence of a variety of types of antagonists to narcotic and inhibitory substances might be expected to reveal, by the relative success of each group in

removing the symptoms, the real seat of the action of magnesium salts. This mode of investigation has again been taken up by Starkenstein in the pharmacologic institute of the German University in Prague.³ His conclusion is that it is not possible to designate the so-called magnesium narcosis as either a purely central or purely peripheral paralysis, but that the irritability of all parts of the nervous system is depressed by magnesium ions. Substances which have been supposed to act only peripherally may exhibit a central effect and vice versa. This is quite in harmony with the latest observations of Auer and Meltzer on the effects of ether on the skeletal motor mechanism.⁴ Contrary to the usual statement that ether and chloroform, when inhaled, do not affect the muscles and nerves, these authors find that inhalation of ether exerts an unmistakable influence on the irritability of these tissues. In many experiments involving the direct stimulation of individual groups of muscles and nerves, the depressive effect of the anesthetic was manifest to such a degree that no tetanus at all was obtainable; even the single contraction of the muscles was often nothing more than a short twitch. This depressive manifestation is readily reversible and prompt if the etherization is not too prolonged or dangerously deep. There are distinct differences in the nature of depressive effects between stimulation of nerve or of muscle.

Auer and Meltzer point out that the decreased capacity to produce a tetanus means an increase of fatigability. The greater loss of tetanus with nerve stimulation than with direct stimulation of the muscle under the influence of ether anesthesia means, therefore, that the inhalation of ether causes a greater fatigability in nerve than in muscle. Increased fatigability of the nerve to stimulation means increased resistance to the passage of impulses or increased fatigability of the nerve-endings, since nerve-fibers are not fatigable as a rule. A greater resistance to the passage of impulses in the nerve-ending than in the muscle-tissue is a curare-like action. Magnesium salts have been said to act essentially like curare. Evidently ether, besides its undoubted central effects, has a similar activity.

Some further bearings of these facts have been brought out by these observations that the peripheral motor mechanism may be profoundly affected by ether inhalation. Githens and Meltzer⁵ have obtained evidence that the phrenic nerve and the diaphragm lose a good deal of their irritability in the course of ether anesthesia and that the toxic action on the

peripheral respiratory mechanism begins at an early stage of the etherization. Surprising as it may seem, chloroform, on the other hand, practically does not affect the irritability of motor nerves.⁶ In experiments lasting sometimes six or seven hours the response to a faradic stimulation of the nerve at the end of the period was a tetanus equal to that obtained at the beginning with a similar stimulus. Only when by the prolonged use of a full dose of chloroform the heart became profoundly affected did the irritability of the nerves also become depressed; but this depression is apparently only secondary, due to anemia and asphyxia, and is not a primary effect of chloroform.

Current Comment

THE URINE IN CARCINOMA

The enormous activity which has been aroused in recent years in the study of cancer, stimulated by the contribution of almost unlimited funds, the erection of special institutes and hospitals, and the promise of personal distinction for those who win success, has unfortunately developed some undesirable aspects. No one can deny that there is a formidable and promising array of talent engaged in the solution of the cancer problems. On the other hand it cannot be concealed that there has been an unduly large output of undigested hypotheses. In many fields of science a theory does little harm and often much good, however short-lived it may be, for it either stimulates the investigators to a rigid examination of its contentions or enables them to use it in the critique of their work. But where hypotheses are likely, as in medicine, to find a speedy translation into the terms of practice, a certain degree of intelligent conservatism is usually preferable to the awakening of false hopes based on unjustified premises. To-day we can record another controverted claim emanating from the clinical study of cancer. The urine of man contains a group of chemical substances of unknown origin and indefinite composition, commonly spoken of as the oxyproteic acids. They represent a small fraction of the nitrogenous content of the urine precipitable by special methods of chemical treatment. A few years ago it was announced in contributions from the First Medical Clinic of the University of Vienna that the oxyproteic acid fraction of the urinary nitrogen is decidedly increased in carcinoma, the augmentation being emphasized as a characteristic of the disease. A revision of the subject in von Fürth's laboratory in Vienna has failed to substantiate this.¹ There are cases in which the usual, or normal, content of 4 per cent. is raised to as high as 9 per cent. This occurs only in the cachectic stages of carcinoma and is found in the severe stages of other diseases such as tuberculosis.

It is not a constant phenomenon, but merely an occasional accompaniment of severe cachexia, whatever its antecedent cause may be.

THE WAR AND THE DRUG-SUPPLY

While American life has not been at once affected in any wide-spread dramatic way by the European catastrophe, all sorts and conditions of men are likely to find it touching them at unexpected points. Physicians, for instance, may find that they are hampered in the writing of prescriptions by scarcity of some drug. This country doubtless would suffer little inconvenience beyond the increase in price if compelled to rely on the resources of this continent so far as most inorganic chemicals and biologic preparations are concerned. As for vegetable drugs, however, aside from cascara, hydrastis and podophyllum, few of therapeutic importance are produced in the United States. This country depends largely on European manufacturers for finished preparations and on European middlemen for crude drugs. Crude drugs from the far East, such as buchu, cinchona, senna, asafetida, rhubarb, opium and aloes, come to us largely through the London and Amsterdam markets. A comparatively small amount of cinchona comes from South America, and, if access to the London and Amsterdam markets is shut off, the South American drug might be obtained direct. While the prices for these substances have advanced, the supply should not be altogether cut off by this war unless it should spread to the East and thus limit production. This year's opium crop in southeastern Europe is said to have been greatly damaged by the recent war in the Balkan States and Turkey. Of imported synthetic drugs and alkaloids, by far the largest proportion come from Germany. Ophthalmologists are likely to feel the result of the interruption of trade with Germany in the withdrawal of supplies of physostigmin, pilocarpin, atropin and homatropin. Other important drugs of German manufacture are strychnin, quinin, caffein, cocain, theobromin, formaldehyd and salvarsan. The involvement of France, the chief source of supply of tartaric acid, and of Austria-Hungary, which with France and the Balkan States supplies us with the essential oils, will affect the drug-supply much less than the isolation of Germany.

PRODUCTION OF MEDICINAL SUBSTANCES IN THE UNITED STATES

We have commented above on the effect of the European war on the drug-supply. We may reckon some gain along with the loss if the war leads to a scrutiny with a view to revision of the United States patent laws, which at present favor the importer at the expense of the American public. The patent laws of Great Britain and some other countries provide that the holder of a patent must, under penalty of forfeiture, begin manufacture of the patented product within the country in a reasonable period of time from the issuance of the patent. An American branch of at least one German house had begun the manufacture of a synthetic product before the war. Others

may find it worth while to manufacture on American soil if the war continues; but if our patent laws had contained a provision similar to that of the British law, we would not now be threatened with temporary shortage or stoppage of therapeutic supplies. Our laws, in addition, permit the patenting, not merely of the process, but also of the product. Therefore the American market is altogether dependent for any given patented product on a single foreign manufacturer. Revision of our patent laws may become a necessity if the European war is not over soon. Another result may be an investigation of the possibility of producing in this country a larger proportion of the drugs used here. The Department of Agriculture has long maintained that, so far as soil and climate are concerned, the conditions are favorable for the growing in this country of many of the drug-plants now imported from abroad. In view of the uncertainty whether or not, under practical conditions, the yield could be marketed profitably, cultivators have naturally been somewhat reluctant to experiment with untried crops; but the stimulus of war prices doubtless will induce some growers to make a trial that will demonstrate which drug-plants are commercially profitable.

THE FATE OF CHOLESTEROL IN THE BODY

Now that cholesterol is no longer viewed with indifference with respect to its physiologic rôle, and its possible functions in a variety of phenomena involving the "lipoids" are conceded,¹ the fate of this interesting compound found so widely distributed in animal tissues is brought up for consideration more prominently than ever before. The exceptional resistance of cholesterol to ordinary reagents, its stability, coupled with the lack of knowledge respecting its precise chemical structure, has served to retard the understanding of what happens when cholesterol disappears in the organism. A "balance" of the cholesterol intake, output and storage has never yet been correctly struck in suitable experiments. It appears quite probable that little, if any, cholesterol is ordinarily synthesized anew.² In the light of this situation even tentative hypotheses are acceptable. From this point of view we refer to the recently developed views of Lifschütz³ in Hamburg. He believes that among the diverse physiologic uses of cholesterol is the function of its disintegration products in the migration of fats in the body. According to him the compound takes up an atom of oxygen—presumably in the blood-stream—and is converted into oxysterol, a substance far more reactive than its natural precursor. But beyond this there are other decomposition products which Lifschütz regards as the mother substance for the non-nitrogenous components of the bile acids. Such a sequence of interrelationships has been postulated before, and the burden of proof still remains with those who propose it.

3. Lifschütz, J.: Der Abbau des Cholesterins in den tierischen Organen (Studie). VI. Mitteilung. (Cholesterin-Gallensäuren), *Ztschr. f. physiol. Chem.*, 1914, xci. 309.

Medical News

ILLINOIS

Medical Staff Organized.—The medical staff of the Galesburg Hospital at its meeting for organization, August 3, elected Dr. Clarence B. Ripley as chief and Dr. Arthur D. Pollock as secretary of the staff.

Work on Epileptic Colony.—The State Board of Administration has ordered a topographic survey of part of the ground selected for the buildings for the new State Epileptic Colony. This work will take probably two or three weeks.

State Hospital Changes.—Dr. Romney M. Ritchey of the Anna State Hospital has been transferred to the Elgin State Hospital.—Dr. George W. Morrow, acting assistant superintendent at the Anna State Hospital, has been succeeded by Dr. Whedon W. Mercer of the Peoria State Hospital, and has resumed his position as ward physician.

Personal.—Dr. Charles B. Horrell, Galesburg, is reported to be detained in Europe by reason of the war conditions.—Dr. Elmer E. Hagler, Springfield, who was recently operated on for appendicitis, has recovered and resumed his practice.—Dr. Albert Weil, Peoria, is reported to be seriously ill with septicemia at Proctor Hospital, Peoria.—Dr. Catherine B. Slater, Aurora, has gone abroad.—Dr. E. W. Fell of the staff of the Elgin State Hospital has resigned to become a member of the staff of the Ransom Sanitarium, Rockford.—Dr. Frederick W. Werner, Joliet, who has been seriously ill with septicemia at Silver Cross Hospital, suffered amputation of his right foot August 11.

Chicago

Personal.—Drs. E. Wyllys Andrews, John B. Murphy, Howard O. Shafer, Harry M. Richter, J. Rawson Pennington and Paul Oliver returned from Europe last week.—Dr. James W. Jobling, formerly pathologist of the Michael Reese Hospital, has been appointed professor of pathology in the Vanderbilt University, Nashville, Tenn.—Dr. George W. Dunlap has sailed for Europe.

Physicians Held in Europe.—Among the Chicago practitioners who are held in Europe by reason of the difficulty in obtaining transportation on account of the war are the following: Donald P. Abbott, Russell M. Wilder, Maurice Pincoffs, Vernon C. David, Charles Davison, Nelson M. Percy, William Fuller, Otto H. Rohrlack, Adolph Hartung, George W. Post, Jr., Winfield Scott Hall, Adolphus E. Bertling, Maximilian Herzog, Kasimir A. Zurawski, George Paul Marquis, Thomas J. Watkins, Norval H. Pierce, Cassius D. Wescott, Junius C. Hoag, Casey A. Wood, Isaac A. Abt, Ira Frank, Samuel Salinger, Adolf Decker, Walter H. Allport, John A. Stahl, Calvin W. Harrison, Frank A. Stahl, Charles H. Solomon, Robert S. Denney, Harry R. Wormley, Emilius C. Dudley, Franklin H. Martin, David Monash, Ernest Saurenhaus, F. Curt Harnisch, Leo M. Czaja, Truman W. Brophy, R. D. MacArthur, Charles M. Robertson, Allan B. Kanavel, Willis O. Nance, Henry R. Smith and Carl Langer.

IOWA

Sanatorium Opened.—The Scott County Tuberculosis Hospital was opened recently with simple ceremonies. The institution represents an investment of \$75,000.

Personal.—Dr. Campbell P. Howard, Iowa City, has been elected vice-president of the American Society for Clinical Research.—Dr. John E. Brinkman, Waterloo, has gone abroad.

Health Officers Given More Power.—The State Board of Health on July 9 adopted a rule regarding quarantine for contagious diseases which gives health officers absolute power in the conducting and handling of these cases.

Work of State Bacteriologist.—During the biennium ending July 1, 1914, the State Board of Health Bacteriologic Laboratory has made 35,433 examinations. About 17,000 of these were for diphtheria, 7,000 for tuberculosis and 4,000 for typhoid fever.

New Officers.—Iowa University Medical Society at Cedar Rapids, July 14: president, Dr. Henry J. Prentiss, Iowa City.—Harrison County Medical Association at Logan: president, Dr. John Tamsiea, Missouri Valley; secretary, Dr. Hans Hansen, Logan.

Workingmen's Compensation Act.—Dr. Wilbur S. Conkling, Des Moines, representing the Polk County Medical

Society, recently conferred with Warren Garst of the Industrial Commission with regard to the cooperation of the state in making the Workingmen's Compensation Act a success.

Hospital Notes.—The Isolation Hospital at Clinton was opened for patients last week. Four beds are provided for patients suffering from quarantinable diseases, and more accommodations will be provided when the upper floor of the building is completed.—Johnson County Medical Society has appointed a committee to secure signatures for the petition for a new hospital for Johnson County. It is proposed to erect a building to cost between \$40,000 and \$50,000.

MARYLAND

Hospital in Hands of Receiver.—Arlington Rest, a sanatorium and private hospital at Arlington, Md., which has been conducted by Dr. Chauncey T. Scudder, has been placed in the hands of a receiver. Dr. Scudder is said to have left the city four weeks ago, thus leaving the institution without an executive head or the advice of a medical expert.

Personal.—Dr. Randolph Winslow and Dr. Walter F. Sowers, Baltimore, have sailed for Europe.—Dr. William C. Stone, Ellicott City, health officer of Howard County, has resigned on his appointment as deputy health warden.—Dr. W. L. Moss, assistant resident physician at Johns Hopkins Hospital, and in charge of the tuberculosis laboratory, has been appointed internist of the Buffalo State Institute for the Investigation of Malignant Diseases, Buffalo, N. Y.—Dr. Thomas F. Keating, Baltimore, has been appointed assistant surgeon in the United States Public Health Service.—Dr. Felix Landois, Johns Hopkins Hospital, captain in the German army medical corps, has been recalled to Germany.

Baltimore

The Fresh-Air Fund.—The Baltimore News Fresh-Air Fund had passed \$7,000 on July 31 and should reach the \$10,000 desired before the end of the season. This fund is for the benevolent activities of the fresh-air farm at Fallston.

State to Help Support Laboratory.—The state of Maryland has agreed to help support the bacteriologic laboratory of the Baltimore Health Department and also to pay the city \$500 rental for accommodation in the new quarters of the Health Department.

President Remsen on Round-the-World Trip.—Dr. Ira Remsen left Baltimore July 16 on a tour around the world by way of the west. He will attend the meeting of the British Association for the Advancement of Science in August and various scientific meetings to be held in New Zealand early in September.

MISSOURI

New Members of Health Board.—The Governor has appointed Dr. Marc Ray Hughes, St. Louis, a member of the State Board of Health to succeed Dr. Ira W. Upshaw, St. Louis, term expired. Dr. T. A. Son, Bonne Terre, to succeed Dr. G. D. Schulz, Cape Girardeau, term expired, and Dr. T. H. Wilcoxon, Bowling Green, to succeed himself.

Home for the Aged.—An anonymous benefactor has donated a home for the aged in Kansas City, and the old Fowler home at Independence and Mt. Gault Avenues has been selected as a site. The house has been remodeled and will contain seventeen rooms in addition to the servants quarters. Four buildings are also to be erected, each of which will contain four modern apartments for aged couples. The institution is to be known as the Kansas City Home for the Aged, and Dr. E. L. Mathias is secretary.

Personal.—Dr. E. S. Carnell, Kansas City, has arrived in London from Vienna, and is awaiting transportation to this country.—Dr. J. C. Humphries, Laredo, is reported to be seriously ill with kidney disease at the hospital in Trenton.—Dr. David Gordon, Chillicothe, was dangerously injured by the overturning of his buggy July 31, in a washout when returning from a personal call.—Janet Reid has been appointed medical director of the Deming Tent Cottage, Deming, N. Mex.—Dr. J. M. Singleton, Kansas City, is reported to be critically ill with heart disease at his farm near Leeds.

NEW JERSEY

Personal.—Dr. Richard H. Dieffenbach has resigned as a member of the Board of Health of Newark.—Dr. George B. Verbeck has resigned as resident physician at the Mountainside Hospital, Montclair.—Dr. Margaret N. Sullivan,

Jersey City, has been placed in charge of the women's ward at the Jersey City Hospital.

State Society Meeting.—At the one hundred and forty-eighth annual meeting of the Medical Society of New Jersey held at Spring Lake, the following officers were elected: president, Frank D. Gray, Jersey City; vice-presidents, Dr. William J. Chandler, South Orange; Dr. Philip Marvel, Atlantic City, and Dr. William G. Schaufliker, Lakewood; recording secretary, Dr. Thomas N. Gray, East Orange (reelected); corresponding secretary, Dr. Harry A. Stout, Winona (reelected), and treasurer, Dr. Archibald Mercer, Newark (reelected). The 1915 meeting will be held in Spring Lake.

Hospital Notes.—The contract for the new medical building for the Mountainside Hospital, Montclair, was awarded July 23. The building will cost about \$100,000.—The former home of Theophilus Zerbrugg, Riverside, who left a half million dollars to found a memorial hospital, has been purchased and remodeled and is to be used as a foundation of the new institution.—Dr. Edward Guion, health officer of Atlantic City, has proposed to Atlantic City the establishment of a tented village for tuberculosis patients on the county farm at Smith's Landing.—The freeholders of Camden County and the county tuberculosis commission inspected the new county tubercular hospital at Ancora. The property includes 81 acres of land on which a sanatorium formerly stood. The building has been remodeled at a cost of \$50,000, and now has accommodations for 100 patients.

NEW YORK

New Officers.—New York Medical Alumni Association of the University of Maryland, fifth annual reunion at Syracuse, July 30: president, Dr. Emory W. Carr, Lyons; secretary-treasurer, Dr. DeLancey F. Bartlett, Fayetteville.

Hospital Surgeons Meet.—The newly organized Hospital Surgeons' Association of Kings County met in Brooklyn, July 21, adopted a constitution and by-laws, and appointed an executive committee consisting of a representative from each hospital to serve for the ensuing year.

Physicians and Casualty Companies Agree.—After a series of conferences between representatives of casualty companies and of the Medical Society of the State of New York, a fixed schedule of charges for service to injured employees under the new compensation law has been agreed on.

Petition for Hospital.—A petition, containing the names of eighty physicians of Steuben County, has been filed with the clerk of the county board of supervisors, asking an appropriation for the purchase of a site for a county tuberculosis sanatorium and for the erection of buildings for the institution.

Austria to Get Serum Here.—Dr. Sigismund S. Goldwater, health commissioner, has received a cablegram from the Serum Institute of Vienna requesting the immediate delivery of 50 liters of tetanus serum for the use of wounded Austrian and Hungarian soldiers. The laboratories of Otisville will furnish the serum.

Aid in Cancer Diagnosis.—The State Institute for the Study of Malignant Disease at Buffalo, N. Y., is prepared to cooperate with physicians throughout the state to undertake to make the diagnosis of all cancer cases throughout the state and states that it will be glad to diagnose all cases from the city of New York sent to the institute. They are desirous that the physicians of the state and of New York City should be made aware of this opportunity.

New Nursing Periodical.—The *Nurse*, announced as "a magazine of scientific nursing instruction and nursing literature," is to be issued monthly by the Nurse Publishing Company, Jamestown, N. Y. The terms are \$2 a year in the United States and dependencies, Mexico and Canada, and \$3 in other countries in the postal union. The first issue (July) consists of 82 pages containing, among other articles, papers on "The Tuberculosis Nurse and the Tuberculosis Problem," by S. A. Knopf; "The Nursing Missicnary," by Bishop W. A. Sellew; "Charity Nursing in a Tenement," "Nursing Method" and "Diet in Sickness and in Health."

Medical Control of Day Nurseries.—At the request of the Department of Health, the committee on public health, hospitals and budget of the New York Academy of Medicine discussed the problem of vaginitis in children as related to public schools, hospitals, day nurseries and other institutions last spring. Following this a committee was appointed to submit recommendations among which were the following:

That those in charge of day nurseries should be informed of the great danger of infection and taught what precautions are necessary; that systematic examination of babies in day nurseries be undertaken by the Health Department to determine the frequency of infection and the measures necessary to diminish it. This matter has been carefully considered by the Health Department and a set of rules for day nurseries in the city of New York have been prepared which provide that each day nursery shall have attached thereto a regular physician of its selection, duly licensed under the laws of the state, and in good professional standing. The set of rules for the guidance of the medical officer calls for the examination of every child before admission to a nursery and for the regular examination of every inmate of a nursery every alternate week. A set of rules governing the matrons of day nurseries has also been provided.

New York City

Hospital Incorporated.—Twenty-two physicians of South Brooklyn have incorporated the Harbor Hospital for the treatment of indigent patients, or those who are able to pay only small fees for hospital care. The institution is housed in a four-story building on Fourth Avenue, and three of the four wards are now ready for occupancy.

Personal.—Dr. William M. Polk has returned from Europe.—Dr. Lewis A. Sexton, resident physician at the Reception Hospital, has resigned to become assistant superintendent of the Johns Hopkins Hospital, Baltimore.—Dr. William S. Irwin, for many years surgeon on the United Fruit Company steamers, has resigned from the service.—The order of St. Sava has been conferred on Dr. Benjamin Jablons by King Peter of Servia.

Extends Campaign for Better Babies.—The New York milk committee is sending a post-card to health officers all over the country telling how the city is working for better babies. The card states that during the past seven years New York City has cut her infant death-rate more than 30 per cent. and that it is actually a safer city for babies to be born in than any other of the ten largest cities of the country. The card states further that no city with an infant death-rate around the 100 mark can afford to be satisfied. The work of the "Better Baby Week" is described, telling how business men were enlisted and financial support secured. The slogan adopted was "Better Babies, Better Mothers, Better City." The card closes with the question, "What is Your City Doing to Advertise 'Better Babies'?"

OHIO

Campaign against Loafers and Spitters.—Chief Wyman of the police department, and Safety Director Vodrey have started a campaign in East Liverpool against loitering and spitting on the sidewalks.

Hospital for Sick Babies.—The Youngstown Visiting Nurse Association has opened a hospital for sick babies, near the Fresh Air Camp in Mill Creek Park with Miss Wallace and Miss Headlings in charge.

Public Health Nurses in Kenton and Findlay.—The joint tuberculosis hospital board of Champaign, Clark, Madison and Greene counties have voted \$1,200 a year for the employment of a public health nurse.

Campaign against Privies.—Dr. Arthur L. Jones, health officer of Lima, has started an active campaign against the thousand odd outhouses in that city. Either such outhouses must be improved to conform to the law or they will be condemned by the board of health.

Many Seals Sold in Ohio.—According to the report of the National Association for the Study and Prevention of Tuberculosis more than 44,000,000 Red Cross Christmas Seals were sold during the recent campaign in the United States. Of these 2,838,892 were sold in Ohio, placing this state second in rank to New York.

State Supervising Nurse.—Miss Margaret Kameron, R. N., state supervising nurse in the Division of Public Health Education and Tuberculosis of the State Board of Health, resigned July 1, after having been identified with the state work for the past two years. When the Ohio Society for the Prevention of Tuberculosis started its first Red Cross Seal Contest in 1911, offering the services of a nurse for one month to each of the twelve cities selling the largest number of seals per capita, Miss Kameron was the nurse chosen to institute the work. Miss Kameron plans to rest through the summer and then intends to take a special course at the Teachers' College, Columbia University.

OKLAHOMA

Still in Europe.—Dr. A. M. Young and Dr. and Mrs. R. M. Howard, Oklahoma City; Dr. and Mrs. W. E. Wright, Tulsa, are marooned abroad.

School for Blind Opened.—Oklahoma State School for the Blind, Muskogee, erected at cost of \$100,000 is now open and 150 students have been enrolled.

Personal.—Dr. W. S. Cary, Rankin, was seriously injured in an automobile accident recently.—Dr. A. L. Walters, Checotah, who was operated on a short time ago for appendicitis is convalescent.—Dr. John H. Barr, Reed, suffered amputation of a limb as the result of an accidental gun-shot wound.

PENNSYLVANIA

Personal.—Dr. Nathaniel S. Yawger has been appointed assistant to Dr. William G. Spiller, chief neurologist to the Philadelphia General Hospital.

New Officers.—Fifth District Medical Society at Brookside Park, York, July 29: president, Dr. William E. Wolff, Arendtsville; secretary-treasurer, Dr. Charles W. Eisenhower, York.

Media's Pure Milk Campaign.—The Woman's Club of Media has started a vigorous campaign to insure pure milk to that town and surroundings. This organization has already provided a visiting nurse for the community.

New Building for State Hospital.—During the next year there will be constructed at Rittersville State Hospital a building for male patients, one for male nurses and an isolation hospital for patients suffering from tuberculosis.

Pennsylvania Relief Fund.—At the semi-annual meeting of the Pennsylvania Railroad Voluntary Relief Association it was reported that during the last fiscal year the fund disbursed \$2,520,847.22. The receipts during the same period were a total of \$2,628,542.66. The fund had total assets of \$2,911,494.93.

Marooned in Europe.—Among the physicians and teachers marooned in Europe are: Provost Edgar F. Smith of the University of Pennsylvania, Edward Robbins, secretary of the Board of Trustees of the University; Drs. E. E. Montgomery, Howard Hansel, William M. Sweet, James M. Anders and William Rodman.

Personal.—Dr. Stacy H. Rinehardt, a member of the staff of the State Tuberculosis Sanitarium, Cresson, has resigned and will practice in Pittsburgh.—Dr. A. H. Bernstein, East Scranton, is detained in Germany by reason of war conditions.—Dr. Benjamin F. Bartho, Mt. Carmel, was operated on for appendicitis at Fountain Springs Hospital, July 31, and is reported to be doing well.—Dr. Harry B. Stryker, Reading, is under treatment in his private hospital for septicemia, and is reported to be improving.—Dr. William J. O'Malley, West Scranton, has started for Columbia, S. A., where he is to be superintendent of the hospital operated by a large copper mining company.—Dr. Joseph C. Doane, superintendent of the Miners' Hospital at Shamokin, has been appointed chief resident physician at Philadelphia General Hospital.

Philadelphia

Baugh Institute of Anatomy to Be Extended.—Mr. Daniel Baugh, the founder and patron of the Baugh Institute, has purchased and added to his original gift, the premises 236 and 238 Pine Street, as an addition to the school, and has given \$5,000 for the improvement and equipment.

More Baby Farms Discovered.—Following the death of three children in an unlicensed baby farm several weeks ago, three other such places have been discovered, where the houses are filthy and the milk was found to contain large quantities of laudanum. The three proprietors, all colored women, were given a hearing before Magistrate Boyle, August 6.

Carnival of Safety.—Safety day will be celebrated by the churches, September 20-27, by the public schools September 23. Carnival Day exercises will be held in Convention Hall, September 26, and the Convention of Safety will meet at Convention Hall, September 26 to 29. The city has taken space for its exhibit; the Pennsylvania Railroad and the Baltimore and Ohio Railroad and the Corporations Utilities Companies are all cooperating.

WISCONSIN

Contracts Awarded for Sanatorium.—Contracts amounting to \$122,720 were let by the Milwaukee County Board, July 31, for work on the Wauwatosa Tuberculosis Sanitarium.

Prosecution for Use of Red Cross.—On the charge of violating the law referring to the use of the Red Cross emblem, fourteen Milwaukee physicians, representatives of railroads, undertakers and liverymen were arraigned in the federal court, July 30. The case has been set for trial on the first Monday in September.

Child-Welfare Staff Appointed.—Health Commissioner George C. Ruhland of Milwaukee has appointed the following staff for the child-welfare health stations: Waluka Park Pavilion, Drs. George Taylor, Frederick Gray, Albert W. Myers, Charles H. Stoddard and Thomas R. Bours; Lapham Park, Drs. George H. Fellman and Clarence F. Hardy; Kosciusko Park, Drs. John N. Rock and Henry J. Gramling.

Health Commissioner Upheld by County Society.—At a meeting of the Milwaukee County Medical Society, July 11, resolutions were adopted urging that the "city government should uphold the commissioner of health in his demand that the ordinance with regard to the test for tuberculosis in cows forming herds that are any part of the milk-supply of the city of Milwaukee, be drawn."

Personal.—Dr. Mazyck P. Ravenel, formerly professor of bacteriology at the Wisconsin State University, director of the state hygienic laboratories, has been appointed a member of the advisory board of the hygienic laboratory of the United States Public Health Service, Washington. Dr. Ravenel ended his duties at Madison, July 1, and has accepted the position of professor of preventive medicine and bacteriology at the public health laboratory of the University of Missouri.—Dr. Thomas F. Thompson has been appointed chief of the sanitary inspection force of the Health Department of Milwaukee.

GENERAL

Railway Surgeons to Meet.—The annual convention of the surgeons of the Rhode Island System will be held in Des Moines, Ia., the first week in September.

Coming Meeting of Ohio Valley Physicians.—The annual meeting of the Ohio Valley Medical Association is announced to be held in Evansville, Ind., November 4 and 5.

Polish Physicians to Meet.—The fourth annual meeting of Polish physicians will be held at Buffalo, N. Y., September 7, under the presidency of Dr. Francis E. Fronczak.

Health Examiners to Meet in Florida.—The annual meeting of the American Public Health Association will be held in Jacksonville, Fla., December 1 to 5, inclusive. The two principal symposiums will be on negro health, and rural health organization and sanitation.

Interstate Society Meeting.—At the annual meeting of the Austin Flint-Cedar Valley Medical Society, held in Cedar Rapids, July 15, the following officers were elected: president, Dr. George Kessel, Cresco, Iowa; vice-president, Dr. Thomas U. McManus, Waterloo, Iowa; secretary, Dr. Charles F. Starr, Mason City, Iowa (reelected), and treasurer, Dr. Will L. Hearst, Cedar Falls, Iowa (reelected). Waverly, Iowa, was selected as the place of meeting for 1915.

The American Red Cross in European War.—At a joint meeting of the International and War Relief boards of the American Red Cross held in Washington, August 5, it was decided formally to tender the services of the society to the warring nations, and plans were initiated for the immediate issuance of appeals for relief funds and for placing medical officers and nurses trained for the work at the disposal of the forces. Announcement has been made that a fully equipped hospital ship carrying physicians, nurses and medical supplies will be sent to Europe, sailing under the Red Cross flag and under protection of the Geneva Convention and Hague Treaties.

Subscription Swindler at Work.—Attention is called to the operation of a swindler who recently has been operating among doctors and dentists, soliciting subscriptions for which he is not authorized. His offers concern generally a combined subscription to *The Literary Digest* and such medical publications as a dictionary, medical clinics and other medical works. Numerous aliases are used in signing receipts. He is described as about 21 years old, 6 feet tall, weighing about 180 pounds. Has black hair, very dark and large black eyes, a deep falsetto voice, and somewhat pale skin. A reward of \$25 has been offered for his arrest. Communications should be sent to the Periodical Publishers' Association, 156 Fifth Avenue, New York City.

The Plague Situation.—Since the report made in THE JOURNAL of August 1, one more case of human plague has been reported in New Orleans. This fourteenth case was a

car cleaner 22 years of age, male, employed at the Louisville and Nashville shops at Girod and Front streets, who was taken ill July 29, with femoral bubo. There have also been discovered eleven additional cases of plague-infected rats, making thirty-two in all. On July 25 the Board of Health of New Orleans, on recommendation of the United States Public Health Service, adopted four ordinances having for their object the prevention of plague in the city and its eradication from infected foci. The first of these ordinances relates to the keeping of fowls and small animals, and provides that such animals can be kept only in rat-proof buildings. The effect of this ordinance is to keep rats away from food given to or left by these animals, thus removing one of the usual sources of food-supply of rats and mice. It also protects pet animals from infected fleas. The second ordinance relates to the position of vessels and water craft of all description at docks and wharves, and the method of loading and unloading; provides that no water craft shall be nearer than 8 feet from any dock or wharf; that all hawsers, chains or lines of any kind be equipped with rat shields or guards approved by the health officer of the city; that gang-plank, staging or other structures intended for loading or unloading, and by which rats might pass between wharves and vessels must not be left down except during actual loading or unloading, and that at these times there must be a guard at each gang-plank or staging to watch for rats and prevent them going to or from the vessels. When it is necessary to load or unload at night in addition to the guard at each gang-plank or staging, proper and sufficient lights must be furnished and the gang-planks must be whitened for a space of 10 feet. Crated cargo or empty barrels or boxes are not to be loaded or unloaded until inspection has shown that they are free from rats. The third ordinance provides that every building, outhouse and other superstructure now erected or hereafter to be erected at New Orleans shall be rat proofed in the manner given in detail in the ordinance. The fourth ordinance provides that the owner, agent and occupant of all premises improved or unimproved in New Orleans shall provide metal, water-tight containers with tight-fitting covers in numbers sufficient to receive the garbage accumulation of forty-eight hours from such premises. The object of the ordinance is to keep the garbage from serving as food for rats. All garbage must be kept in the prescribed garbage containers.—The Iowa State Board of Health through its secretary, Dr. W. L. Biering, Des Moines, has started a campaign against rats and other rodents, in order to reduce to the minimum the risk of bubonic plague.—P. A. Surg. J. M. Gillespie, U. S. P. H. S., has been ordered to New Orleans and has been assigned to the charge of the fifth sanitary district which embraces the territory bounded by Elysian Fields Avenue to Jordan Avenue, and North Claiborne Avenue to the river.

CANAL ZONE

Personal.—Surgeon James C. Perry, U. S. P. H. S., has resigned as chief quarantine officer, and has been granted a leave of absence of a year, which he will spend in traveling.—Major Thomas L. Rhodes, M. C., U. S. A., has been transferred to the Panama Canal service, and has been appointed superintendent of the Colon Hospital.

Better Accommodations at Detention Stations.—The two-story building at the east end of the Colon Hospital, formerly occupied by officers, has been turned over to quarantine service as a detention station for the first-class passengers. The building contains forty rooms in addition to a large dining-room. The old detention station will be continued to be used for steerage passengers.

Private Hospitals.—The chief health officer of the Canal Zone issued on July 9 a circular setting forth that as a maintenance of private hospitals in the cities of Panama and Colon interferes seriously with the supervision and control of the department of health over sanitary matters, it is ordered that no private hospitals shall be established or maintained in the cities of Panama and Colon; any such hospitals being conducted in these cities shall be discontinued. Any one, who as a physician, owner or person in charge of any private hospital in the cities of Panama or Colon, shall establish or maintain any such hospital after the prorogation of this order should be fined a sum of not exceeding \$500 for each day after the continuance of such hospital.

Morbidity and Mortality for June.—The chief officer of the Canal Zone reports that during June the admission to hos-

pitals and quarters was 1,511 or a rate of 381.09 per 1,000 per annum, as compared with 407.92 for the preceding month, and 472.50 for the corresponding month of 1913. The total number of deaths was 20 and of these 13 were due to disease. Two deaths were due to lobular pneumonia, organic diseases of the heart and tuberculosis. The disease causing the most admission and non-effective rates in hospitals was malaria with 62 per 1,000 per annum. The next highest admission rates in order were for venereal, digestive and respiratory diseases. These four classes of diseases caused 51 per cent. of all admissions. The admission rate to hospital and death-rate for black employees were 139.79 and 3.67 for 1,000 per annum as compared with 350.66 and 1.43 for white employees. The non-effective rate disease and injuries for black employees was 10-20 per 1,000 as compared with 18-67 for white employees, and the admission rate for hospitals for malaria was 53.23 per 1,000 per annum for blacks as compared with 143.37 for whites.

FOREIGN

War Interferes with International Congresses.—Among the international congresses that were to have been held in Europe this summer and fall are the congress on medical electrolgy and radiology, Lyons, July 27; on ophthalmology, St. Petersburg, July 28; conference on tuberculosis, Berne, September 2; the International League against Epilepsy, Berne, September 5; on neurology, psychology and psychiatry, Berne, September 7; the congress on criminal anthropology, Budapest, September 14; on occupational diseases, Vienna, September 21, and the congress of International Association for Sexual Research, Berlin, October 31.

Clashing International Congresses.—The propaganda committee in charge of the International Medical Congress, planned to be held at Munich in 1917, has issued an appeal to other scientific organizations begging them to arrange their meetings so as to leave that date open for the above international gathering. As at present planned, the International Surgical Association is to hold its fifth meeting at Paris in 1917, and numerous national annual meetings are arranged for that year in Germany and elsewhere. In order to prevent this dissipation of forces the committee urges other organizations to postpone their annual meetings that year and gather at the International Medical Congress, particularly as "radiotherapy of tumors," "biologic reactions," "diagnosis and treatment of tetanus," and "thrombosis," which are the subjects appointed for discussion at the Surgical Congress are all of special interest to internists as well. The committee says that it would be still better for the above organizations to hold their meetings as sections of the great medical gathering. This is what the anatomists have already decided on; the International Congress on Anatomy has been affiliated with the International Medical Congress as a section of the same. As the International Surgical Association meets every three years and the Medical every four years, once in twelve years they will clash. The appeal is signed by J. F. Lehmann, the well-known publisher of medical works, chairman of the propaganda committee.

CANADA

Association Meetings.—The Alberta Medical Association at its recent annual meeting elected Dr. Robert G. Brett, Banff, president, and Dr. J. G. Clark, Calgary, secretary-treasurer. Next year's convention will be held in Banff.—The Canadian Public Health Association promises to have a very successful convention at Port Arthur and Fort William, September 10 to 12.

Personals.—Among Canadian doctors caught in Europe when war was declared are: Mr Irving H. Cameron, William P. Caven, Duncan N. MacLennan, Richard A. Reeve of Toronto. Dr. A. Orr Hastings, Toronto, was successful in returning on the *Olympic*. There are still a large number of Canadians of the medical profession still on continental Europe as well as in England unable to return to their native land. Several have offered to serve in the British army.—Dr. Harvey Clare, assistant superintendent of the Toronto Hospital for the Insane, has been appointed medical director of the new Detention Hospital just opened in Toronto.—Dr. Keith Simon has been appointed pathologist to Grace Hospital, Toronto.—Dr. Walter S. Bloom, Kingston, has been appointed professor of biologic chemistry at Harvard University.—Dr. George S. Ryerson, Toronto, has been made an Honorary Chief of the Six Nations Indians with the name of Ra-de-ri-yoho—"Man-Who-Fights-His-

Way."—Dr. O. C. Gruner, assistant professor of pathology at McGill University, Montreal, has resigned and returned to England.

Manitoba Sanatorium for Consumptives.—The third annual report of the above institution includes the annual report for the year 1913 as well as the financial report for the year ending March 31, 1914. In February an infirmary building was opened with capacity for 27 patients. The full capacity of the institution is now 118, nearly twice of that when it was opened in 1910. In 1911 the patients admitted were 168; in 1912, 189; and in 1913, 232. This sanatorium aims to provide for the care of incipient cases for the whole province, leaving the advanced cases to the King Edward Municipal Hospital in Winnipeg. The patients in the sanatorium on Jan. 1, 1913, were 67; the patients admitted during 1913, 232; the patients discharged, 203; remaining, 96; and the total number admitted since sanatorium was established, 686. Of the 203 discharged, 1.5 per cent. were untreated; 8.3 apparently arrested; quiescent, 28.6; improved, 34.5; unimproved, 15.3; died, 11.8. In addition to the usual hygienic-dietetic means of treatment tuberculin was given to more than half the patients discharged, to 12 for less than one month; to 47 for from one to three months; to 68 for more than three months. Of 127 treated with tuberculin, there were 31 incipient, 44 moderately advanced and 52 far-advanced. In 1912 there were 492 deaths from tuberculosis in Manitoba, representing 8.5 per cent. of the total number of deaths, or 103.8 per 100,000 of the population. In Winnipeg during the years 1909 to 1912, the deaths have fallen from 150 to 96.

LONDON LETTER

THE CLINICAL CONGRESS OF THE SURGEONS OF NORTH AMERICA

LONDON, July 29, 1914.

Clinical Work of the Congress

The thousand American surgeons who have congregated here for the fifth clinical congress are unanimous in calling it a success. Though the twelve general hospitals and medical schools and the thirty special hospitals visited are scattered over the wide area of this city every visitor seemed without difficulty to reach his destination and see the work and man in which he was specially interested. At the hospitals lists of the operations were displayed on the doors, and as all the seats had been allotted there was no overcrowding. At first there was a run on the clinics of certain surgeons and the tickets for seats were exhausted in a few minutes; but on the second day the men seemed to seek the particular work in which they were interested rather than particular men, and the seats of no clinic were exhausted for half an hour. This was evidently due to the discovery that the London surgeons maintained a good general level of work and that ability was not in the hands of a few. It was generally agreed that in some respects the technic was not up to the American level. Thus in the theater of one surgeon of world-wide reputation it was observed that he did some work which should have been done by his nurses. However, a considerable improvement in methods was noted, and the tendency for American surgeons coming to Europe to visit German clinics in preference to English was declared to be passing away. Our visitors were full of praise for the ample preparations made at the hospital for their reception. Some idea of the vast amount of material for demonstrations will be gathered from the fact that at one hospital alone no fewer than 170 operations have been arranged.

A clinic which attracted great attention was Mr. Arbuthnot Lane's at Guy's Hospital. Before a crowded audience he removed the colon for intestinal stasis and removed wedges of bone and inserted a plate in a case of malunion of fracture of both bones of the forearm. While operating he kept up a running commentary which often traveled far from the case and was enlivened by witticisms which convulsed the audience. "Nature never does anything right; never give her a chance." "My views on intestinal stasis are so simple that they are not understood." "As long as a disease is medical and remains in the hands of the physician it is never understood; it is only when it comes into the hands of the surgeon that it is understood." The various membranes which are now described in peritoneal cavity and attached to the names of various persons he declared that he had described years ago. The thing to do was not to bother about giving them names but to understand that they were all adaptations due to Nature's attempt to counteract the effects of gravity in the upright posture. Every one of us was the result of adaptation

to our surroundings. Anatomists did not realize this sufficiently and the subject was taught in an absurd fashion. If persons would only study the anatomy of the coal heaver and the shoe-maker they would begin to understand.

Another clinic which attracted great attention was Mr. Berry's at the Royal Free Hospital. Mr. Berry removed an exophthalmic goiter under local anesthesia with novocain. He also removed a parenchymatous goiter. He laid emphasis on the importance of exact hemostasis. Another operation followed with great interest was removal of a large malignant tumor from the pharynx with ligature of the external carotid artery. He operated for cleft palate by median suture with mattress sutures and no lateral incision. Mr. Berry did not like the flap operation and never performed it. He never saw a patient who spoke well some years afterward, although he had for long asked those who did it to show him one.

The Opening Session

Instead of the usual social functions, the evenings are devoted to papers and discussions. After a presidential dinner given by Dr. Franklin Martin, the formal opening of the congress took place at the Hotel Cecil. Sir Rickman J. Godlee, ex-president of the Royal College of Surgeons, in an address of welcome invited the delegates to a reception at the college where there was the most important museum in the world. They would show the delegates some of the treasures which they would select as far as possible to illustrate clinical facts. Dr. J. B. Murphy, president of the congress, said the work to be conducted this week was a colossal undertaking. Such a task had never before been undertaken by the congress away from home. American surgeons would return with a high impression of London surgery. High as they had esteemed it before, they would esteem it higher still. They would return with an admiration and affection for the profession and people of this great land, and with a feeling that science was a brotherhood that extended round the globe.

GREETING BY AMERICAN AMBASSADOR

The American Ambassador, Mr. Page, extended a warm greeting to the many distinguished citizens of the United States present. He said he need not tell them that they were heartily welcome to London. Their English friends had shown them that. One of the most distinguished teachers of surgery in this country remarked to him that he frequently told his students that no man had a right to consider himself well started in the profession of surgery unless he had been to the United States to see the skill that American surgeons possessed. Now that 1,000 American surgeons found it well worth while to come to England to see how the distinguished surgeons of this kingdom did their work, he could say, "honors easy." He assumed that Englishmen and Americans were anatomically alike, and in the process of time, with a better acquaintance, they would become more and more politically akin. It was a great joy for them to know that at no time in the history of these two great nations was there ever such a cordial and complete understanding of each other as there was at the present time.

DR. RODMAN'S ADDRESS

Dr. W. L. Rodman, President-Elect of the American Medical Association, said that while the congress was not an integral part of the Association, its members were also members of the latter. Hence what concerned them could not fail to receive the sympathetic attention of that great body, the largest medical organization in the world, to whom they all owe their first and best allegiance. Great and varied as have been the activities of the American Medical Association, it had not hitherto specially concerned itself with postgraduate instruction. Its work had been in other spheres, and who would say it had not been well performed? That splendid organization through its various standing committees or councils had accomplished a mighty work in the decennium. The Council on Medical Education had in that short time done more than had been accomplished in the previous century, so that now American schools were fully abreast of those anywhere. The Council on Health and Public Instruction had carried its beneficent work into every state of the Union, compelling all to recognize that, as the public health was the greatest asset of the people, artificial barriers in the nature of state lines must vanish, and where all of the people were so vitally concerned, federal control was essential. A member of the American Clinical Association had told him that the visits of this body to the various clinics of our own and other countries had so impressed some of the members

that the conception of an American Congress of Surgeons resulted. It was natural and generous that the few who had profited by the clinical work of others should, in turn, wish to see a higher standard of clinical efficiency throughout the country. Hence this congress with its first meeting in Chicago in 1910; in Philadelphia the following year; then in New York; to meet again in Chicago in 1913 with an enrolment of more than 4,000. He traced the development of the American College of Surgeons and said that this body, supplementing the Clinical Congress of Surgeons and the American Medical Association, would fill an honorable rôle in the standardization of surgery throughout the world.

Injuries to the Knee in Sports

In the division of general surgery, Mr. Robert Jones of Liverpool read a paper on "The Internal Derangements of the Knee" with special reference to the derangement of the cartilage to which football players and cricketers are liable. He had chosen this subject because little had been written about it in America. It was a surprise to him, because their games, like our own, were rough and we in England knew to our cost that American youths were skilled and strenuous. He was credibly informed that the anatomy of the knee joints of American youths differed but little from our own, and he was forced to conclude either that their cartilages were more securely placed than ours or, which was most unlikely, that the condition was not so generally recognized as it should be. By far the most common derangement of the knee was injury to the internal semilunar cartilage. In nearly all cases the cartilage was displaced inward, and on those rare occasions in which a protrusion had been felt from the outside it was due to hemorrhage following a tear, localized bruising of tissue, or buckling of cartilage, accompanied by effusion, which gave rise to an irregular outline of the articular margin. The most constant symptom of a displaced or fractured semilunar was a sudden inability to extend the knee. The most frequent cause of the displacement or fracture was strain thrown on the internal lateral ligament while the knee was flexed and the tibia rotated outward. The force necessary to cause the derangement in a first injury was usually severe, and the pain acute. The injury might often be encountered on the football field. All movements of the cartilage must be prevented until union of the torn structures was complete, and no lateral strain must be allowed until the lateral ligament, so often injured, had had time to effect a recovery. The injured joint should be treated by complete rest in full extension for four or five weeks. Instead of this, the patient was usually allowed to get up and walk in a week or a fortnight. This was a grave mistake. He refused to operate in any case immediately after the first displacement, as so large a proportion of these patients recovered under appropriate treatment; nor did he encourage operation in cases in which the recurrent trouble was painless and was never followed by effusion in the joint. But he strongly advocated operation when the recurrence was sometimes followed by acute symptoms, and he encouraged it in all recurrent cases in which a strenuous athletic life was a means of livelihood or a physical necessity. Operation was a positive necessity in the case of men who worked among moving machinery, or stood in positions where a yielding knee might mean disaster.

Laryngofissure

In the division of surgical specialties, E. Schmiegelow of Copenhagen, Denmark, read a paper on the "Results of Operations (Laryngofissure) for Cancer of the Larynx." He showed the excellent results which could be obtained in cases in which cancer attacks the vocal cords. He warmly recommended the operation of splitting the larynx, commonly called laryngofissure. This operation was founded in England through the efforts of the late Sir Henry Butlin and Sir Felix Semon, to both of whom Schmiegelow paid a warm tribute. His results showed a lasting cure of more cases than can be proved with cancer in any other part of the body.

Sir St. Clair Thomson gave statistics by which it appeared that he had not lost a case from this operation, and that some patients were alive and well ten years afterward. He pointed out that Schmiegelow was able to record more cases than any other surgeon had ever done in any city of the British Empire. It looked as if British inventions had to go abroad and be born again before they were accepted in the land of their birth. The public did not seem to realize the importance of hoarseness or the profession to know what excellent results could be secured by laryngofissure. He made an

appeal for an expert examination of the vocal cords in any case of hoarseness which did not clear up within three weeks. His own statistics showed 20 per cent. of lasting cures for intrinsic cancer of the larynx. Many of these cases were shown in King's College Hospital.

(To be continued)

PARIS LETTER

PARIS, July 24, 1914.

Personal

Dr. Couvelaire, agrégé, has been appointed professor of clinical obstetrics at the Faculté de médecine de Paris, vice Dr. Pinard, retired.

The Académie des sciences has just awarded a prize of 3,000 francs (\$600) to Dr. H. Vincent, professor at the Ecole d'application de médecine et de pharmacie militaires de Val-de-Grâce, for his work on the typhoid bacillus and typhoid fever. The La Caze prize (10,000 francs, \$2,000) was awarded to Dr. Gley, professor at the Collège de France, for his works on physiology.

At its session on July 21, the Académie de médecine elected Dr. Mairét national associate. Dr. Mairét is professor of the clinic of mental and nervous diseases at the Faculté de médecine de Montpellier, and has been national correspondent in the section of pathologic medicine since 1894.

Lectures on Eugenics

I have already spoken of the formation of the Société française d'eugénique, which publishes a special magazine (THE JOURNAL, Jan. 18, 1913, p. 221). This society will organize, at the beginning of the school year, a series of lecture courses in eugenics at the Ecole des hautes études sociales. M. Edmond Perier, director of the Muséum d'histoire naturelle, will show the relations which exist between eugenics and biology; Dr. Apert, physician at the Andral hospital, will discuss the questions of heredity related to those of eugenics; Dr. Papillault, professor of sociology at the Ecole d'anthropologie, will show how, thanks to eugenics, a well-defined selection may be made; Dr. Pinard, former professor of clinical obstetrics at the Faculté de médecine de Paris, will study eugenics and child-culture; Dr. Weiss, professor at the Faculté de médecine de Paris, will discuss eugenics in its relation to physical culture; Dr. Schreiber, head of the clinic affiliated with the Faculté de médecine de Paris, will show how one may, how one ought to understand eugenics from the point of view of marriage; Dr. Roussy, director of scientific research at the Ecole des hautes études, will study eugenics and the perfecting of the human race.

The Publication of Case Histories, and Professional Secrecy

The conference of lawyers of the Paris supreme court recently discussed the question as to whether or not the physician who publishes observations made at a hospital in a scientific magazine without having asked permission of the patient has violated the obligation of professional secrecy. The conference decided in the negative.

The Esperantist Congress and Physicians

The tenth international congress of Esperanto will be held at Paris, August 2-10, 1914. On this occasion the Association médicale espérantiste universelle, which counts among its honorary members Professors Bouchard, Richet, Gariel and Broca, will send numerous delegates from different nations to Paris. The meetings will be held in one of the amphitheatres of the Faculté de médecine. Technical questions of professional interest will be publicly discussed in Esperanto.

Death of Paul Reclus

Dr. Paul Reclus, professor of clinical surgery at the Faculté de médecine de Paris, whose death was noted in this department last week, was 67 years old, was a member of the Académie de médecine, and last year a commander of the Legion of Honor.

Paul Reclus produced considerable scientific work. He wrote a manual of external pathology in collaboration with Kirmisson, Bouilly and Peyrot, a treatise on surgery in collaboration with S. Duplay, a treatise on surgical therapeutics in collaboration with Emil Forgue and a book on medico-chirurgical practice—all classics to-day. The name of Reclus is associated with local anesthesia by cocaine and novocain and more recently with that of the disinfection of wounds by tincture of iodine and with the conception of cystic disease of

the nipple. He was a prudent and conscientious surgeon and a remarkable teacher.

Election of Dr. Magnan to the Vice-Presidency of the Academy of Medicine

On July 28, the Académie de médecine elected Dr. Valentin Magnan vice-president (who will automatically become president in 1915) in place of the late Dr. Duguet. Dr. Magnan is physician at the Asile Sainte-Anne, president of the Société médico-psychologique and author of a thesis on the relation between general paralysis and insanity which was crowned by the Académie de médecine in 1867.

The Congress for the Advancement of Science

Circumstances have made the Congress for the Advancement of Science held this year at Havre, a Franco-English scientific affair. A large number of members of the British association accepted the invitation of the French association. At the opening session an interesting address was delivered by Sir William Ramsay, president of the delegation from the British association. One of the bonds which unite England and France, he said, was science: "The immortal name of your Pasteur is associated with that of our Lister. I do not exaggerate when I say that to these two men the world owes a debt greater than that to any others. They have saved millions from death. They have saved more lives than the most bloody wars have destroyed."

EMIGRATION AND HYGIENE

In the section of hygiene, Dr. Clerc, maritime sanitary physician, read an interesting paper on emigration. He suggested that an international conference be held to fix uniform conditions for emigration and to secure the return to the country of their origin of all emigrants not allowed to enter the country to which they went. This resolution was unanimously adopted.

Serious Poisoning by Boric Acid Dressing

While wet boric acid solution dressings are harmless, this is not true of dry dressings of powdered or crystallized boric acid. On July 22, Dr. Savariaud reported to the Académie de médecine, a case of a child of 8, deeply burned in the abdominal wall and thighs, whose wounds were powdered with boric acid. The same evening signs of serious intoxication (headache, vomiting, pulse 120, etc.) manifested themselves. The next day after another dressing with boric acid, the symptoms of poisoning were accentuated and diarrhea, prostration and hypothermia appeared. For some days the child's life was in danger; it would certainly have been lost if the boric acid dressings had not been entirely discontinued.

During thirty years, Savariaud has found record of nine deaths from boric acid poisoning.

Offensive Familiarity Toward Hospital Patients

Complaints have been addressed by patients to M. Mesureur, director of the general administration of the Assistance Publique that the employees of the hospitals and the medical students *tutoied* the patients. [The *tutoiement* is the use of the singular (tu, toi) in place of the plural pronoun of the second person (vous). It is used to express familiarity, somewhat as we would use the Christian name, that is, to intimate and inferiors.] M. Mesureur has ordered directors of hospitals to put an end to such misplaced and humiliating familiarities, especially because hospital patients are temporarily in a position where they are unable to protest.

BERLIN LETTER

BERLIN, July 25, 1914.

Personal

Our well-known professor of anatomy, W. Waldeyer, celebrated the fiftieth anniversary of his doctorate July 20.

Dr. Abel, a member of the Prussian medical state department, has received a call to succeed Professor Gärtner at the Hygienic Institute at Jena. Abel was formerly privat-docent of bacteriology in Greifswald.

Professor Albrecht of Berlin has been called to the ear clinic at Tübingen as successor of Wagenhäuser.

The Frankfurt University

The plans have been made to have the new university of Frankfurt-on-the-Main opened October 18 in the presence of the Kaiser. The announcement of lectures just published shows that almost all of the teaching places (Dozentenstellen) are already filled. Only one regular professor is assigned

for each department. In the majority of cases, the medical men already at work at Frankfurt in the municipal and other hospitals have been appointed as professors, such as Schwenkenbecher for internal medicine, Rehn for surgery, Walthard for gynecology, Herxheimer for dermatology, Edinger for neurology, Ehrlich for experimental therapy, etc. To date only the chair for legal medicine has not been filled.

Specialist and General Practitioner

The Mecklenburg Physicians' Association (Aerzte-Vereins-Bund) at its last session adopted the provision in its medical code of ethics that the simultaneous designation physician and specialist physician is not allowable. A similar provision exists in the codes of other medical associations.

Conviction of Dr. Billfinger

The president of the Association of Antivaccinationists of Germany, Sanitary Councilor Billfinger, was sentenced by the Medical Court of Honor for the kingdom of Saxony to a fine of \$250 (1,000 marks) and deprivation of the active and passive franchise in the medical chamber (*Aerztekammer*) for three years because he accepted the position of medical director of the drugless therapy institute—*Naturheilstalt*—of the notorious quack, Bilz, in spite of the fact that he must have known that absolutely intolerable conditions prevailed there in the treatment and care of the patients. As I informed you some time ago, the Bilz Sanatorium was closed by the police on account of these conditions, which were combined with moral danger to the patients.

Prize Offered by the Prussian Academy of Sciences

A prize of \$1,250 is offered for the best study of "Experience as a Factor in Perception." The exact subject is stated as follows: "The share of experience in observations of the human senses is to be systematically investigated and presented. It is not necessary to collect all the individual facts in physiologic and psychologic literature, but the various forms of sense perception are to be defined as carefully as possible according to the manner and limit of their activity, and the common factors and conformity to law in the various fields of the senses are to be set forth. Exact repetition of the observations which are utilized is essential. Extensive independent experimental investigations of decided value are desired." The prize amounts to \$1,250 (5,000 marks). The competing articles may be in German, Latin, French, English or Italian. They must reach the bureau of the academy in the usual form, before Dec. 31, 1916.

International Public Health Work in Jerusalem

More than a year ago, under German initiative, an international health office was established in Jerusalem under the direction of Mühlens, the scientific assistant in the Hamburg Institute for Marine and Tropical Diseases. According to a recently published article of Nocht, director of the Institute for Marine and Tropical Diseases, the support of the institute at Jerusalem at present is shared in common by the German Committee for the Campaign against Malaria in Jerusalem; by Nathan Strauss of New York and by the Society of Jewish Physicians and Scientists for Sanitary Interests in Palestine. The German committee supports the general department for combating malaria, and its chairman is at the same time the director of the institute. Nathan Strauss supports the hygienic and bacteriologic department of which the heads are Drs. Brünn and Goldberg. The Society of Jewish Physicians and Scientists has taken over the department for protection against rabies, originated by the German committee, the director of which is Dr. Behan. An accessory department for the prevention of eye diseases (director, Dr. Feigenbaum) has been added.

The most important task of the office is the malaria campaign which must be prosecuted in three directions. It is necessary, first, to eradicate the parasites in man by the thorough treatment of patients and also of the apparently healthy germ-carriers. As a general rule, the children in Jerusalem are infected, as is usual in old malarial foci. The treatment of schoolchildren with quinin, begun by Mühlens with great success, should be thoroughly carried out. The tactful method of Mühlens easily overcame the superstition and fear of the Mohammedans, their wives and children. Only in the beginning did the taking of blood meet any opposition. The success of the antimalaria treatment in the schools was soon apparent. The general attendance at school which was formerly much disturbed by sickness, became much more regular. The children were more active and their

work was better done. The number of new attacks of malaria grew remarkably less. Quinin, generally in a sugar-coated or tasteless preparation, was readily and regularly taken by the children. The success with schoolchildren facilitated the introduction into families and homes. Dr. Brünn secured the same results in the special Jewish quarters.

Even in the dry season, Jerusalem is a city much infested with mosquitoes, especially with anopheles, the malaria carrier. Their destruction is the second task in the campaign against malaria. In Jerusalem mosquitoes, in addition to the dark dwellings of the inhabitants, infest the numerous cisterns which are of large extent, very old, defectively built and easily accessible to the mosquito. Jerusalem is still exclusively supplied with rain-water for drinking purposes. The cisterns are also the breeding-places of the anopheles mosquito, and many swarm with mosquito larvae. If the cisterns were screened against mosquitoes, the mosquito plague, under present conditions, would cease in Jerusalem.

By closing the cisterns to mosquitoes and doing away with the present unhygienic method of drawing water by pails which are let down through larger or smaller openings, generally left uncovered, and by replacing the pails by pumps in well-covered cisterns, it has been possible already to diminish the mosquito plague to a remarkable extent in many parts of Jerusalem.

Here the third form of the malaria campaign must begin by the education of the population, awakening their interest and winning their active cooperation in the removal of nuisances, and by permanent inspection of the cisterns by a health commission (mosquito commission). The authorities of the city have, moreover, made a permanent annual contribution to the work of the health office.

The campaign against tuberculosis has proved to be much more difficult and less promising; it will also require much larger means. Particularly the improvement of the incredibly wretched dwellings of the native population, Jews as well as Mohammedans, will require the efforts of many years and the expenditure of considerable funds. Moreover, carrying out a long period of curative treatment such as is necessary in tuberculosis will be found to be very difficult.

The campaign against other infectious diseases in Jerusalem will depend chiefly on the introduction and progress of a general communal health movement, of which hitherto there have been only very small beginnings. According to the latest newspaper reports, the supply of the city with good spring water by a system of water-pipes has now been undertaken by a French company. The accomplishment of this plan would render the suppression of typhoid, dysentery and other infectious diseases much easier, especially among the poorer population, who depend on the old cisterns often contaminated with water from the streets. It remains to be seen whether the large institutes supported by European funds will give up their beautiful, roomy and entirely unobjectionable cisterns after the establishment of the water system, and especially whether the removal of the anopheles nuisance will be particularly assisted by the introduction of a public water-supply.

Marriages

LOUIS FLOYD MURRAY, M.D., Santa Fe, N. Mex., to Miss Adelaide Dickinson of Washington, D. C., at Albuquerque, N. Mex., July 27.

DONALD LONSON STILWELL, M.D., Detroit, Mich., to Miss Maude Marie Kellerman of Pittsburgh, Pa., June 27.

OSCAR WILLIAM LINDORFF, M.D., to Miss Hedwig Charlotte Wahlburg, at Chikungelang, China, June 29.

ACHILLES EDWARD DAVIS, M.D., to Miss Josephine K. Robinson, both of New York City, July 30.

FRANK HUGHES LALLY, M.D., Varina, Ia., to Miss Mary Catharine Barry of Jackson, Neb., July 15.

WILLIAM EDWIN JOINER, M.D., to Miss Alice Belinda Johnson, both of Seattle, Wash., July 30.

CHARLES ROSS BENNETT, M.D., Graham, Ky., to Miss Anna J. Patton of Hartford, Ky., June 23.

SETH FENELON ARNOLD, M.D., Boston, to Miss Irl Gann of Benton, Ark., at Boston, June 27.

WILLIAM J. BUCK, M.D., to Miss Catherine Mary Hampton, both of Gainesville, Fla., July 8.

Deaths

Philip Matthew Wagner, M.D. Ohio Medical University, Columbus, 1896; a Fellow of the American Medical Association; of Canal Dover, Ohio; president of the Tuscarawas County Hospital; a specialist on diseases of the eye, ear, nose and throat; a member of the board of education for ten years; local surgeon of the Baltimore and Ohio System; once a member of the city council; a member of the Seventy-Sixth General Assembly; while studying in Germany, was taken ill with cholelithiasis in Berlin, and died while undergoing operation for this condition, July 24, aged 46.

Grace Greenwood Prior Yankauer, M.D. Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1898; a Fellow of the American Medical Association; assistant surgeon to Mt. Sinai Hospital, New York City, and a member of the staff of the New York Eye and Ear Infirmary; was instantly killed in an accidental fall from the window of her apartment in New York City, July 28, aged 40.

Frank Ely Osborne, M.D. University of Nebraska, Lincoln and Omaha, 1903; postmaster of McAllen, Tex.; a member of the State Medical Association of Texas; formerly physician to the Nebraska Institution for Feeble-Minded Youth, Beatrice; while attempting to cross the tracks of the St. Louis, Brownsville and Mexico Railroad, near Donna, Texas, in his automobile, July 30, was struck by a train and killed, aged 36.

Adelaide M. Griffin Tucker, M.D. Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1895; member of the staff of the Bradford City Hospital; a member of the Medical Society of the State of Pennsylvania; for several years a specialist in diseases of the eye, ear and throat of Bradford, Pa.; died in the Bradford Hospital, July 24, after a surgical operation, aged 43.

Francis M. Bennett, M.D. New York Homeopathic Medical College, New York City, 1883; for many years a member of the school board of Springfield, Mass.; a member of the American Public Health Association; and a member of the staff of the Wesson Memorial and Wesson Maternity Hospitals; died at his home in Springfield, about July 29, aged 57.

Thomas E. Heenan, M.D. University of Pennsylvania, Philadelphia, 1868; for many years in the diplomatic service of the United States; for twenty-three years consul at Odessa, Russia; and later consul at Newchwang, China; Warsaw, Russia, and Fiume, Austria-Hungary; died in the latter city, June 26, from heart disease, aged 62.

George Irvin Barwick, M.D. University of Maryland, Baltimore, 1894; a member of the Medical and Chirurgical Faculty of Maryland; for many years a practitioner of Kennedyville, Md.; but for the last four years a resident of Baltimore; died at his home in that city, July 25, from angina pectoris, aged 45.

Thomas Carman Hodge, M.D. Atlanta College of Physicians and Surgeons, 1908; of Atlanta, Ga.; a member of Southern Medical Association and the Medical Association of Georgia; assistant to the chair of anatomy in his Alma Mater; died in a sanitarium in Atlanta, July 28, aged 29.

Arthur Parker Sargeant, M.D. University of Minnesota, Minneapolis, 1913; of Minneapolis; formerly intern in the Minneapolis City Hospital; while endeavoring to save a woman from drowning in Lake Carlos, near Alexandria, Minn., July 30, was drowned, aged 28.

William Henry Carpenter, M.D. Philadelphia University of Medicine and Surgery, 1869; Dartmouth Medical College, Hanover, N. H., 1876; of Boston; a specialist on diseases of the eye, ear, nose and throat; died at his home in Brookline, Mass., July 23, aged 77.

John Irving Russell, M.D. Willamette University, Salem, Ore., 1909; a Fellow of the American Medical Association and proprietor of the Lakeview, Ore., Sanitarium; died in the Good Samaritan Hospital, Portland, Ore., July 25, from nephritis, aged 28.

Robert P. Page, M.D. University of Pennsylvania, Philadelphia, 1861; a member of the medical society of Virginia; surgeon in the army throughout the Civil War; died at his home in Berryville, Va., July 26, aged 76.

Charles Allen Holbrook, M.D. Bennett Medical College, Chicago, 1878; of Dorchester, Neb.; died in the Nebraska State Hospital, Lincoln, July 14, from senile debility, following a cerebral hemorrhage, aged 73.

Sherman M. Beeman, M.D. Washington University, St. Louis, 1881; for many years a practitioner of Chillicothe, Mo.; died at the home of his son in Denver, Colo., July 27, from senile debility, aged 77.

John Henry Griffith, M.D. Jefferson Medical College, 1870; a Fellow of the American Medical Association; twice mayor of Philipsburg, N. J.; died suddenly at his home in that city, July 28, aged 72.

William T. Benson, M.D. College of Physicians and Surgeons, Kansas City, Kan., 1902; of Kansas City; died at the home of his father in that city, July 29, from appendicitis, aged 34.

James Ball Rogers (license, Louisiana) for many years a practitioner of Allen Parish, La.; died at his home near Kinder, La., July 16, from disease of the heart and kidneys, aged 76.

Charles E. Booth, M.D. Rush Medical College, 1872; for twenty-five years a practitioner of Minneapolis; died in the Asbury Hospital in that city, July 25, aged 74.

George W. Williams, M.D. University of Louisville, Ky., 1878; for thirty-one years a practitioner of Pittsburg, Kan.; died at his home in that city, July 29, aged 64.

Charles Thomas Buffum, M.D. College of Physicians and Surgeons in the City of New York, 1877; of New York City; died at Wainscott, L. I., July 29, aged 61.

Lee Osborne Scott, M.D. Rush Medical College, 1905; a member of the Illinois State Medical Society; died at his home in Rockford, Ill., June 26, aged 36.

Herman Berberich, M.D. Jefferson Medical College, 1901; of Philadelphia; died from heart disease while surf-bathing at Wildwood, N. J., July 26, aged 36.

Gustave A. Heidel, M.D. St. Louis College of Physicians and Surgeons, 1897; died at his home in Muscatine, Iowa, July 16, from heart disease, aged 42.

Herbert Forrest Williams, M.D. Hahnemann Medical College, Philadelphia, 1896; died at his home in Philadelphia, July 26, from tuberculosis, aged 42.

Carl G. Lindeblad, M.D. Rush Medical College, 1908; formerly of La Grange, Ill.; died in his apartments in Albuquerque, N. Mex., July 30, aged 33.

James Turner Persons, M.D. University of Alabama, Mobile, 1890; died at his home in Bayou Labatre, Ala., about July 18, from heart disease.

Hilary F. Oliver, M.D. University of Pennsylvania, Philadelphia, 1858; of Birmingham, Ala.; died in Woodlawn, Ala., May 18, aged 76.

Sanford B. McClure, M.D. Cincinnati College of Medicine and Surgery, 1874; died at his home in Allegany, N. Y., June 30, aged 79.

Albert Roberts Pyne, M.D. University of Toronto, 1887; died at his home in Toronto, July 6, from cerebral hemorrhage, aged 65.

Ezra John Guyott, M.D. Hahnemann Medical College, Chicago, 1882; died at his home in Utica, N. Y., June 22, aged 60.

Almas P. Bogue, M.D. Georgetown University, Washington, D. C., 1872; died at his home in Washington, May 10, aged 66.

Alger William Rice, M.D. New York University, New York City, 1880; died at his home in Marion, Mass., May 12, aged 59.

James Raizon, M.D. Rush Medical College, 1891; died at his home in Trinidad, Colo., July 15, from heart disease, aged 59.

Christopher Johnston, M.D. University of Maryland, Baltimore, 1880; died at his home in Baltimore, June 26, aged 58.

Alfred Royce Brundage, M.D. Albany (N. Y.) Medical College, 1890; died at his home in Chicago, July 20, aged 54.

John L. Van Alstyne, M.D. Albany (N. Y.) Medical College, 1862; died at his home in Binghamton, N. Y., May 18.

Joseph William Russell, M.D. Jefferson Medical College, 1907; died at his home in Cleveland, Ohio, July 15, aged 30.

William Watson McCulloh, M.D. University of Pennsylvania, 1898; died at his home in Baltimore, July 19.

John Joseph Mitchell, M.D. Harvard Medical School, 1902; died recently at his home in Charlestown, Boston.

Joseph Remi Tanguay, M.D. Detroit Medical College, 1871; died at his home in Detroit, July 20, aged 69.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

PODOLAX

"Podophyllin With the Gripe Taken Out" Proved a Phenolphthalein Nostrum

L. E. Warren, Ph.C., B.S.

CHICAGO

"PoDoLax" is being extensively advertised as a laxative by the E. E. Sutherland Medicine Co. of Paducah, Ky. The claim is made that:

"PoDoLax is not an accidental discovery nor an Indian Remedy."

It is claimed that on the other hand:

"It is the result of hard study by the brightest minds in the medical profession. The pleasant taste is the effect of the work of a first-class chemist, so combining the drugs of the prescription as to eliminate the objectionable taste and at the same time retain their strength."

The name "PoDoLax" is apparently intended to suggest that podophyllin is the chief constituent of the remedy, and this implication is quite unmistakably conveyed in the following expression found in one of the advertisements for the preparation:

"PODOLAX

Podophyllin with the Gripe taken out."

Also in a circular devoted to the exploitation of PoDoLax and other nostrums the following statements are found:

"Now a new name is before the world, which is made up from the words 'Podophyllin' and 'Laxative.'"

"'PoDoLax' is the word.

"'PoDo' from Podophyllin—

"'Lax' from Laxative or gentle rather than purgative.

"PoDoLax is Podophyllin with the gripe taken out. The only objection ever made to Podophyllin was the griping, and that is entirely overcome in PoDoLax.

"PoDoLax is humanity's oldest and best proven remedy, made pleasant.

"Mandrake is the Biblical term and is first mentioned in Genesis also in the songs of Solomon.

"Some of the doctors . . . still give Podophyllin because ever since the days of Jacob, Mandrake, as it was called in the Bible, has been the best of all to start the Bile.

"A harmless, never-failing, natural remedy, as pleasant to take as maple syrup. . . ."

Aside from these statements and the declaration on the label that PoDoLax contains 6 per cent. of alcohol, no information concerning the composition of the preparation is given. Since from its physical appearance it seemed improbable that the preparation could contain much resin of podophyllin it appeared worth while to examine a specimen of PoDoLax with the view of determining its laxative constituents.

The product is sold in 5-ounce panel containers which retail at fifty cents. The preparation examined was a dark brown, syrupy liquid having an aromatic, sweet taste and an odor like a mixture of anise, saffrafras and wintergreen. It contained a considerable quantity of finely divided crystalline material in suspension. Some of this was separated by filtration, washed with water and identified as phenolphthalein by the usual tests. Another laxative substance was also present, which appeared to be an extract of senna. Large quantities of sugar (sucrose) were present. Small quantities each of alcohol, ammonium compounds, oil of wintergreen and possibly other volatile oils were also found. A determination of alcohol gave 4.47 per cent. by volume. The residue on drying amounted to about 71.5 gm. per hundred c.c. Podophyllin was absent or not present in more than traces. Phenolphthalein was determined and about 1.6 gm. per hundred c.c. found. This is equivalent to about 1.8 grain in each directed dose of PoDoLax. Whether or not other laxatives are present in small quantities matters

little since phenolphthalein and senna are the essential medicinal ingredients, of which the former probably predominates. From the results of the examination it appears that PoDoLax is an aromatized syrup containing phenolphthalein in suspension and fortified by the addition of an extract of senna. Phenolphthalein is a synthetic compound made from coal-tar. Therefore, PoDoLax cannot be a "natural remedy" and to advertise such a preparation as

"Podophyllin with the gripe taken out"

is to offer it under claims that are misleading, false and fraudulent. That the manufacturer knows this is perfectly evident from the fact that these lying claims do not occur on the label of the trade package or in the circulars which accompany it—where they would come within the purview of the law—but are found in advertisements and in circulars which reach the consumer in other ways. Since the Biblical mandrake, *Mandragora autumnalis*,¹ has no botanical or therapeutic relation to the American mandrake, *Podophyllum peltatum*, the attempt to give Biblical sanction to the exploitation of PoDoLax by connecting it with the mandrake of the Bible is to be expected from the usual ignorance, stupidity and dishonesty of the "patent medicine" exploiter.

To sum up:

1. PoDoLax is sold under the claim that it contains podophyllin, whereas it contains none, or at least not more than traces. Its chief medicinal ingredient is phenolphthalein.

2. The false claims concerning the composition of PoDoLax do not occur on the labels of the trade package or in the circulars which go with it, but are made in other ways. This shows the exploiter to be aware of the fraud and deceit practiced in making and selling the nostrum.

Correspondence

"Abuse of Normal Salt Solution"

To the Editor:—In THE JOURNAL, July 25, 1914, p. 307, appeared an article on the "Abuse of Normal Salt Solution" which prompts me to make a few remarks on scientific fairness.

This article, like not a few others of recent years, is apparently an effort to discredit the work of Prof. M. H. Fischer, and incidentally to introduce a subject that has nothing to do with the title, namely, the use of glucose solutions as substitutes for normal saline. This article is, in one particular respect, quite unlike most of the others of similar trend; that is to say it makes use of hearsay evidence, faulty case reports, and undigested references to the literature.

I shall make no attempt to discuss all the references cited by the author. Many of them deserve citation in connection with edema and nephritis, but also many of them do not. One of the most noteworthy instances is the paper of Newburgh (*Boston Med. and Surg. Jour.*, 1913, clxix, 40). Newburgh's work was a perfectly satisfactory bit of observation which almost, if not completely, supported Fischer's contentions, though Newburgh did not interpret it that way, owing perhaps to his (at that time) ignorance of the physiochemical action of salts on colloids. Otherwise he would have known that to discontinue digitalis and magnesium sulphate and place his patients on alkaline sodium chlorid solution would not tend to improve their condition.

The really laughable citations are two—one from Bain (*Brit. Med. Jour.*, Oct. 5, 1912) and one from Stevenson

(same journal, Dec. 28, 1912, p. 1749). Bain's case was one of a child who was edematous. Bain was told that the child may have eaten salt. The physician ordered that the child should have no salt with its food and that all salt should be placed beyond its reach. He prescribed a *simple mixture* of magnesia and compound tincture of cardamom, and castor oil at bedtime. Four days later the edema had disappeared. Stevenson's patient was a young married woman who suffered from general edema "for which no cause could be found except the excessive use of salt." Stevenson was told that the whole family [of the patient] was very much addicted to salt eating. He ordered the salt discontinued and the edema disappeared. In the same volume of the *British Medical Journal* (p. 1057) is the report of another case which Dr. Litchfield missed. It is by Midelton, who says that he had a patient with exophthalmic goiter who suffered from excessive edema. He was told that she ate large quantities of salt. This habit he ordered discontinued. After that the edema "lessened greatly." Midelton concludes his report as follows: "Patients who are fond of highly salted food sometimes refuse to give it up. I know of several such who have puffy eyelids and slight edema of the feet, especially at night." And cases such as these are used to help nullify the serious work of scientific men!

The work of Lepine (*Rev. de méd.*, 1911, xxxi, 744) quoted in the article I am discussing is not a report that has any value in this connection, except in a very roundabout way, for Lepine's conclusion is that while the state of chlorid retention has something to do with hysteric cases, yet the pathogenic action of the chlorid retention is complex and certainly indirect.

Blum, also quoted (*Sem méd.*, Sept. 13, 1913; abstr., THE JOURNAL, Oct. 21, 1911, p. 1408), says that many symptoms and disturbances following injections are due to sodium chlorid, and refers to the salt fever of infants. He says it is better to add a little alkali to the salt solutions.

Geyster (*Am. Med.*, 1914, lvii, [N. S. 9]), after urging that normal saline has a wide field of usefulness, says: "It would be strange if a remedy as potent and yet as simple as the normal salt solution should escape indiscriminate and thoughtless use by the inexperienced." He then goes on to tell what he means by that and makes very much the same points in one direction as does Professor Fischer.

Burnett's experiments (*Jour. Biol. Chem.*, 1908, iv, 57) have nothing to do with the case, except to lengthen the bibliography, because he used seawater, and because he used it in enormous doses given in short periods of time. For instance, he gave a 2,200-gm. rabbit 400 c.c. of a one-sixth molecular sea-water in three-fourths of an hour. Beside, he concludes that the magnesium in the sea-water is responsible for the glycosuria which follows its injection.

I shall not continue with these references of Litchfield. I am glad to admit once more that some of the others have a bearing on the problem. But that is not the point. The point is that a large proportion of the references quoted by Litchfield have no bearing on the problem, but have for one or another reason been perversely used, and that is not scientifically fair.

Moreover, when the criticisms of a man's work are cited as references against his work, his responses to criticism surely should be used, as, for instance, Fischer's response to the almost ridiculous papers of Moore (THE JOURNAL, Oct. 19, 1912, p. 1429), and his response to the unsigned attack by a writer in the *Archives of Internal Medicine*.

As for the "Controverted Theory of Nephritis" (THE JOURNAL, June 20, 1914, p. 1971), the title of that editorial was stupid, since the article it quoted had to do with the method of production of the albumin in the urine, that is, with a symptom and not with the basic condition.

Professor Fischer's book did not "calmly disregard all of the work just mentioned," but considered it in the light of his experimental work, discarded most of it so far as applications were concerned, and then proceeded to show to the holders of the older theories that when their patients were about to die from lack of salt and alkali, he could save them

1. *Mandragora autumnalis* is a poisonous, alkaloid-bearing member of the nightshade family (Solanaceae) and is a close relative of belladonna. It was prized by the ancients in the belief that it would cure barrenness, but has never been employed as a cathartic. *Podophyllum peltatum* is a native of America, belongs to the barberry family (Berberidaceae) and contains no alkaloids. Although its cathartic properties have been known by the American Indians from prehistoric times the plant was not described by botanists until 1731 (Catesby: *Natural History of Carolina, Florida and the Bahama Islands*, 1731, i, 24). Consequently it could not have been known to the writers of the Bible.

by using a newer method. In other words, his theory *works* in properly selected cases. And all he has done has been to pass the so-called authorities, when he found that what they said was not true.

Professor Fischer, and all really scientific research workers, will welcome criticism if it be fair. He was the first to suggest that not all that he believed might be true (*THE JOURNAL*, Sept. 5, 1908, p. 830). But he should not be burdened by the prejudice which accompanies and follows authority.

The burden of proof is on those of the opposition, and it will take much time and experimentation to successfully balance the work that has been done while they were talking. Many of them will have to learn the new language, which is slowly but surely replacing the antique dialects of medicine, before they can hope to even understand what is being talked about.

In conclusion, it is pleasant to add that Professor Fischer was one of the workers who have been instrumental in showing why glucose is valuable and on what its action in certain types of acidosis depends (*Science*, 1913, xxxviii, 486). It is to be hoped that no one will discontinue its use on this account. PAUL G. WOOLLEY, M.D., Cincinnati.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

SEALING OF MUSEUM JARS—PREVENTION OF MOLDS IN KAISERLING SOLUTION

To the Editor:—1. Please give me a satisfactory formula for sealing museum jars.

2. Also, some manner, or change in method, which will guard against the growth of molds in Kaiserling solution.

HERBERT V. L. SAPPER, Norman, Okla.

ANSWER.—1. It is the opinion of several authorities, to whom this question has been referred, that those jars with metallic lid clamps and jars having ground stoppers are adequate for the purpose. Sealing is unnecessary as it often becomes essential to change the fluid on the specimens, a difficult process when the jars are sealed. In some places the use of museum jars, except in cases of very large specimens, has been abandoned. Reference may be made to an improved method of mounting specimens on watch glasses (Day, L. E.: Improved Method of Mounting Museum Specimens, *American Veterinary Review*, October, 1913, p. 66).

2. It has been found that the addition of a few crystals of thymol to the Kaiserling solution, at the time of making, is a good preventive against the growth of molds. About 1 gm. of thymol to a gallon of fluid is sufficient. Another precautionary measure is boiling of the solution just previous to its use.

ROSS JONES AND NOGUCHI BUTYRIC ACID TESTS

To the Editor:—1. Are the Ross Jones test and the Noguchi butyric acid test reliable in determining the diagnosis of syphilis?

2. How do these tests compare with the Wassermann test?

F. S. WHITE, M.D., San Antonio, Tex.

ANSWER.—1. The Ross Jones test and the Noguchi butyric acid test are not specific tests for syphilis, but indicate simply an increase in the amount of protein in the cerebrospinal fluid.

2. These tests, when positive, are not of as great significance as the Wassermann test, that is, they do not certainly indicate syphilis.

The Summer Question.—Summer brings baby problems. Babies live in a different world than adults and sudden changes in food, excessive heat and other shocks to their vibrating vitality may easily swing the pendulum to the danger side. A baby is a living "factory" of possibilities and we should see that it is a business necessity to keep his "works" at the utmost efficiency.—*Bull. Chicago School Sanit. Instr.*

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ALBERTA: Edmonton, September 15. Registrar, Dr. Cecil E. Race, University of Alberta, Edmonton.

IOWA: Des Moines, September 10-12. Sec., Dr. Guilford H. Sumner, Capitol Bldg., Des Moines.

NEW YORK: September 22-25. Chief of Examination Division, Mr. Harlan H. Horner, Department of Education, Albany.

Arkansas Homeopathic May Report

Dr. Scott C. Runnels, secretary of the Homeopathic State Medical Board of Arkansas, reports the oral, practical and written examination held at Little Rock, May 27-29, 1914. The number of subjects examined in was 12; total number of questions asked 120; percentage required to pass was 75. The total number of candidates examined was 8, all of whom passed. Two candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Kansas City Hahnemann Medical College (1912)	80,	(1914)	77, 82.2, 83.1, 85.4, 87.5, 91.7, 95.4.

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Georgetown University School of Medicine.....	(1891)	New York
Cleveland Homeopathic Medical College.....	(1904)	Ohio

The following questions were asked:

ANATOMY

1. Define anatomy. 2. How many bones in the upper extremities? Name them. 3. Name the branches given off the arch of the aorta. Where is the innominate artery and what are its divisions? Name the branches of the external carotid. 4. Name the divisions of the digestive tract, and describe the duodenum. 5. Where is Scarpa's triangle? Give its boundaries and name the important structures contained therein. 6. Give the origin and insertion of five muscles. 7. Name the cranial nerves and give their distribution. 8. Give the blood-supply of five organs of the body. 9. Locate and describe a femoral hernia and give its coverings, beginning at the surface. 10. Give the fetal circulation.

PHYSIOLOGY

1. Give the composition, reaction and uses of blood. 2. Name the secretions of the alimentary canal, their reaction and functions. 3. What is the physiologic function of the liver? 4. Describe urea, its occurrences, variations in the quantity excreted and recognition in the voided urine. 5. What is the function of the first cranial nerve?

CHEMISTRY

1. Give the chemical name and formula of (a) common table-salt, (b) marble, (c) plaster of Paris, (d) borax, (e) blue vitriol, (f) soot, (g) vinegar, (h) verdigris, (i) tartar emetic, (j) sugar of lead. 2. Define (a) base, (b) acid, (c) salt; give examples. 3. Name ten elements used in their pure state in medicine. 4. Write the equation of the reaction when pure wood alcohol is burned; (b) when corrosive sublimate and potassium iodid meet in solution. 5. What is meant by (a) hard water, (b) soft water? (c) how may hard water be made soft? (d) What does the presence of an abnormal amount of chlorine in water indicate? (e) How would you determine its presence? 6. Name five substances used as antiseptics or disinfectants and give their chemical formula. 7. What is grain alcohol? Give formula. Name some substances from which it is derived; describe the process of preparation; name some contaminations and give mode of determination. 8. Give three tests for sugar in urine. 9. Give five tests for albumin in urine. 10. Give composition of human milk.

PATHOLOGY

1. What diseases of the mother may be transmitted to the fetus? 2. Define anemia, hyperemia and leukemia and give examples of the cause of each. 3. Difference between congestion and inflammation. 4. How does sarcoma differ from carcinoma? 5. What determines the benign or malignant character of a new growth? 6. Describe the etiology of malaria. 7. Give pathology of different forms of pleurisy. 8. What diseases are attended with ulceration of the intestines? 9. Describe changes in cirrhosis of the liver. 10. Distinguish between hematuria and hemoglobinuria; causes of each.

BACTERIOLOGY

1. Define following terms: coccus, bacillus, spirillum, obligate anaerobe, facultative anaerobe and give examples of each. 2. Name the organisms commonly found in (a) furunculosis, (b) tonsillitis. 3. Define germicide, antiseptic, asepsis, sterile and disinfectant. 4. Define parasite, saprophyte, spore, flagellum, mycelium. 5. Name five culture-media. 6. Name pathogenic organisms having exogenous toxins. 7. Give dif-

ferential characteristics of organism causing (a) diphtheria; (b) tuberculosis. 8. Name ten diseases caused by specific organisms. 9. Name ten diseases caused by organisms but not specific. 10. Give brief outline of (a) Widal test; (b) Wassermann.

HYGIENE

1. Mention five preventable diseases. 2. (a) Mention five satisfactory disinfectants and give indications for their uses. (b) What gases are most efficient as disinfectants? 3. (a) How can malarial districts be made healthy? (b) How can *Anchylostoma duodenale* districts be made healthy? 4. Describe in detail the sanitary precautions necessary in typhoid fever. 5. Describe the agency of the ptomaines in inducing disease, and the disorders produced by them.

DIAGNOSIS AND PRACTICE

1. Give differential diagnosis of pneumonia, bronchitis, pleuritis. 2. Give treatment of pneumonia, including indications for three remedies. 3. Give etiology, symptoms and treatment of pericarditis. 4. Define gastritis. Give diagnostic indications. Outline treatment. 5. Describe typical typhoid fever to a fatal termination. 6. What is cerebral anemia? What is cerebral hyperemia? Differentiate. 7. Give cause, symptoms and terminations of poliomyelitis anterior. 8. Measles: Describe a case and give differential diagnosis from scarlatina. 9. Give differential diagnosis of variola and varicella. 10. What is malaria? Describe, briefly, different types of malaria, and give clinical diagnosis between continuous type and typhoid fever.

MATERIA MEDICA

1. *Apis mellifica*: Give method of preparation of this remedy, and give two characteristic symptoms. 2. *Belladonna*: Give the common name of this drug. Give the brain symptoms indicating its administration. Name the alkaloids of belladonna. 3. *Conium maculatum*: Give characteristic symptoms calling for its use in disease of the urinary organs. 4. *Ipecacuanha*: Give symptoms calling for this remedy in disease of the digestive tract. 5. Give characteristic symptoms of lachesis. 6. *Opium*: Name two alkaloids and give their physiologic action. 7. *Podophyllum peltatum*: Give the aggravations and ameliorations indicating administration of this remedy. 8. *Rhus toxicodendron*: Give the characteristic symptoms of this drug. 9. *Sulphur*: What are the general indications for this remedy? 10. *Veratrum viride*: Give the abdominal symptoms calling for the administration of this remedy.

THERAPEUTICS

1. Give indications for chamomilla, mercurius vivus and arum triph. in stomatitis. 2. Differentiate acute catarrhal laryngitis, croupus laryngitis and diphtheria, and outline treatment for diphtheria. 3. Differentiate indications for aconite, hyoscyamine and kali carb. in pericarditis. 4. Give etiology and symptoms of chronic nephritis; mention three leading remedies and give definite indications for each. 5. Differentiate enterocolitis and dysentery. Briefly outline general treatment and name at least two remedies in each case. Give distinct indications. 6. Outline general management of a case of pneumonia, in an adult. Name several remedies, giving indications briefly. 7. Give indications for *Aethusa cynapium*, bismuth and ipecac in vomiting. 8. In treatment of la grippe give indications for *Rhus tox.*, *Eupatorium perf.* and pyrogen. 9. Differentiate indications for *Kali bich.*, *Nux muscata* and *pulsatilla* in stomach disorder. 10. What is erysipelas? Outline treatment.

SURGERY

1. Patient in state of coma, what might it be? Give differential diagnosis. 2. Give ten methods of controlling hemorrhage. 3. Give five methods of anesthesia and their contra-indications. 4. Reset a dislocated inferior maxilla. 5. Name the dislocations of the shoulder-joint. 6. Mention ten varieties of fracture of a long bone. 7. State most common seat of fractures of the clavicle; give treatment. 8. Differential diagnosis of appendicitis and renal colic. 9. Describe four varieties of club-foot. 10. What is Colles' fracture; Pott's fracture?

OBSTETRICS

1. Give brief description of female pelvic anatomy. Name diameters. 2. Give diagnostic points and methods of determining early pregnancy. 3. Give general outline of attention necessary during the puerperal period. 4. Name several of the disorders incident to the period of pregnancy. Give treatment indicated. 5. Give varieties of placenta praevia and treatment. 6. Give etiology of antepartum hemorrhage and treatment. 7. What is third stage of labor? Give management. 8. Give management of breech presentation. 9. Name several complications incident before labor. 10. From beginning of labor until flow of milk is established, what conditions might be met that would definitely indicate *pulsatilla*, *aconite*, *secale cor.*, *ipecac* and *phytolacca*. Briefly outline indications.

GYNECOLOGY

1. Differentiate simple from gonorrheal vaginitis and give treatment for each. 2. Give causes and treatment of ovaritis, acute and chronic. 3. Define metrorrhagia. (b) Name two of its most common causes prior to the menopause. (c) What would you suspect should it occur subsequent to the same? (d) How would you verify your suspicions? 4. Give symptoms, diagnosis and treatment for chronic endometritis. 5. What are the nervous manifestations of amenorrhea? 6. Give etiology and treatment of salpingitis. 7. Give symptoms and treatment of retroversion of the uterus. 8. Name the uses of the uterine sound. Enumerate contra-indications and dangers attending its use. 9. Give merate contra-indications and treatment of pelvis cellulitis. 10. Describe etiology, symptoms and treatment of pelvis cellulitis. 10. Describe the pathologic effects caused by lacerations of cervix and give all reflex disturbances therefrom.

Book Notices

DIGEST OF COMMENTS ON THE PHARMACOPEIA OF THE UNITED STATES OF AMERICA (EIGHTH DECENNIAL REVISION) AND ON THE NATIONAL FORMULARY (THIRD EDITION) for the Calendar Year Ending Dec. 31, 1912. By Murray Galt Motter and Martin I. Wilbert. Paper. Pp. 495. Hygienic Laboratory Bulletin No. 93. Washington: Government Printing Office, 1914.

The preface announces that this, the eighth bulletin of the present series, rounds out three decades of the systematic compilation of comments and criticisms on the Pharmacopeia of the United States. The original publications were based on the sixth edition of the Pharmacopeia, which was published at the close of the year 1882, and the digests have been continued more or less regularly since that time. The material included in the present bulletin has been arranged with a view of conserving space, and despite the fact that it appears to include more references than any of the former publications, the number of pages has been materially reduced. The bulletin is aptly defined by the compilers as an elaborated index of current literature relating to pharmacopeial articles, and from this point of view should be of value to all physicians who are in any way interested in the progress or development of drug therapy. The number and the nature of the comments on the German Pharmacopeia that are quoted indicate a real live interest on the part of the physicians as well as pharmacists of that country in the composition and possible uses of the Pharmacopeia, and should be an incentive to the professional men in this country to emulate. Among the more interesting compilations found in this volume is a table showing the highest and lowest maximum, single and daily doses of widely used potent drugs and preparations included in the maximum dose tables of the several pharmacopeias. The figures given in this table indicate that even with articles that are more or less uniform, so far as the purity and strength of the preparations are concerned, there is nevertheless a marked variation in the amount of drug that is considered harmful in different countries. Current discussions on international uniformity in the standards, requirements and tests for widely used or potent medicaments and the desirability of restricting the scope of the Pharmacopeia to really useful drugs and preparations reflect rather a live interest in these vitally important features of pharmacopeial development. These discussions also appear to indicate an earnest desire to provide for future medical students a safe and sane foundation of knowledge regarding materia medica subjects. The quotations from published reports of officials entrusted with the enforcement of laws relating to the production and sale of drugs indicate that much of the material that is now being sold as medicine is either directly harmful or absolutely useless and that greater care and activity is needed on the part of all concerned to secure reasonable uniformity and purity in the medicines dispensed to patients.

ORGANIC CHEMISTRY FOR STUDENTS OF MEDICINE. By James Walker, LL.D., F.R.S., Professor of Chemistry, University of Edinburgh. Cloth. Price, 6 shillings. Pp. 328. London: Gurney & Jackson, 1913.

The name of James Walker occupies an enviable position in the realm of physical chemistry. Perhaps no other elementary text-book on this subject has been so well received by teachers as that of Walker's, and this speaks all the more for the author, because all recognize the difficult task of presenting the physical side of chemistry in a suitable manner, and yet in a suitably sized text-book. It was a matter of some surprise to note that Walker has recently written a book covering an entirely different field; in fact, he so restricted the name of his text that probably he could have selected no other subject which so thoroughly excludes physical chemistry. Nevertheless, in view of the ability shown in his previous works an equally good and serviceable book might have been expected, but anticipations have not been realized. The book, as the name suggests, is written primarily for the benefit of the medical student who is taking his first course in organic chemistry; but it cannot be recom-

mended as a text especially adapted for medical students, or any other kind; in fact, it is believed that there are many other organic chemistry texts that more nearly approach the demand of an American school. The subject-matter is presented in a rather uninteresting and monotonous manner, while in a few places the English is such as to be quite confusing. Although the book is recent, it cannot be termed "modern." For example, bivalent carbon, a plausible explanation for the poisonous effects of cyanids and carbon monoxid, is not brought forth; no attempt is made to explain molecular rearrangements, a subject with which every student must later come into contact in physiologic chemistry, and very little insight is given concerning the mechanism of reactions, which rather detracts from the book. References are not given, and in certain instances, names which usually are correlated with certain reactions are omitted. Typographic errors occur in a few places, as the formula for metaphosphoric acid (p. 29) and picric acid (p. 183). A few physical data are incorrect, as in the case of the melting-point of pure formic acid.

A matter of great concern to the American teacher in a medical school is the consideration of proprietary medicines. In this book, the proprietary names of medicines are emphasized instead of the clinical names which reveal their actual constitution, and thus the medical student who uses the book is liable to prescribe names rather than drugs. Urotropin, for instance, is clearly brought forth, while hexamethylen-amin, the official name is relegated to the background.

TEXT-BOOK OF LOCAL ANESTHESIA FOR STUDENTS AND PRACTITIONERS. By Prof. Georg Hirschel, I Assistant in the Surgical Clinic, Heidelberg. With an Introductory Preface by Prof. Dr. Wilms. Translated by Ronald E. S. Krohn, M.D. Cloth. Price, \$2.75 net. Pp. 181, with 103 illustrations. New York: William Wood & Co., 1914.

The practice of local anesthesia which has received such extended application in recent years resolves itself into a knowledge of a few anesthetic substances and a minute and exact knowledge of the distribution of the nerves and the technic by which nerve-trunks can be made accessible. For the obtunding agent Hirschel chooses only novocain combined with an epinephrin preparation. Morphin is recommended as a preliminary injection, occasionally to be accompanied by scopolamin. The discussion of remedies, instruments and injection technic is brief, occupying less than ten pages, while the remainder of the book is taken up with the description of the methods of applying anesthesia to the various regions of the body. The descriptions are elucidated by a number of excellent plates showing anatomic relations. The poorly developed state of local anesthesia of the female genital tract is indicated by the little attention given to this phase of the subject. The work may be characterized as quite conservative, presenting no method that has not been well worked out. The application seems to be made wholly to operative work, for although the use of local anesthesia for the relief of pain in laryngeal tuberculosis and obstinate neuralgia is applied on the same anatomic principles, the important developments receive no notice. As a guide to the practice of local anesthesia previous to operation, the work will easily take first rank. The translation is excellent and the value of the work has been enhanced by the addition of an index.

PRACTICAL THERAPEUTICS. Including Materia Medica and Prescription Writing, with a Description of the Most Important New and Nonofficial Remedies passed on by the Council of Pharmacy and Chemistry of the American Medical Association. By Daniel M. Hoyt, M.D., Assistant Physician to the Philadelphia General Hospital. Second Edition. Cloth. Price, \$5. Pp. 426, with illustrations. St. Louis: C. V. Mosby Company, 1914.

While this is not an exhaustive work on pharmacology, it is constructed on such a practical basis as to give it good reason to claim to be a useful one. It aims to found the indications for drugs on their physiologic action, which is explained clearly and briefly. The classification is made according to the principal purpose for which the drug is employed, and the chief space is given to those agents which are likely to be most used by the physician. This discussion

of medicinal agents, together with a chapter on proprietary medicines and dispensing, constitutes the book proper. This book may perhaps be accorded the honor of being one of the first, if not the first, to deal with the patent medicine evil in a separate chapter as of importance to the physician who is to prescribe drugs. The page given to the subject of dispensing is quite inadequate. A fuller discussion of this subject, which is also of great importance to a large class of physicians, would have been very desirable. The rest of the book consists of an appendix which is nearly as large as the body of the work and may even overshadow it in importance. It contains an authorized reprint of the greater part of New and Nonofficial Remedies for 1913, and a bibliography which is singularly brief and certainly much fuller on some subjects than on others. Thus "Benzol in Leukemia" has twenty references while "Emetin in Amebic Dysentery" has only one. Such a bibliography can be of little value to student or teacher. An index of drugs follows which gives briefly the properties of the official drugs with reference to the page of the book where each is discussed. The book throughout follows the unusual custom of printing both terms of the ingredients of prescriptions with initial capitals; thus, Acid. Boric. Carelessness in the use of Latin endings and in the printing of prescriptions is one of the minor blemishes of the work. Despite these criticisms, we repeat that the author has produced a useful work which ought to have its share in the coming regeneration of therapeutics.

TWELFTH ANNUAL REPORT OF THE BUREAU OF SCIENCE, PHILIPPINE ISLANDS. Paper. 1913.

This handsomely printed report of 130 pages, exclusive of the abundant plates and other illustrations, gives only a brief sketch of the tremendous activities of the bureau and its energetic personnel. It is a splendid record of the practical application of scientific study to the health and material welfare of a tropical country in which the problems and the opportunities are both on a tremendous scale of bigness. It is hardly possible to take the space even to enumerate the varied lines of work in which the bureau has been engaged for the past year, but they range from intensive studies of plague, cholera and dysentery and their bacteriology, description and classification of the flora and fauna of the islands, etc., to the fisheries, the making of cement, lime and sugar, and research work in the discovery of new products useful in science and the arts, etc. The report is accompanied by a booklet, made up largely from the information contained in the report, indicating the possibilities of legitimate industry and commercial exploitation in the islands.

SURGERY: ITS PRINCIPLES AND PRACTICE FOR STUDENTS AND PRACTITIONERS. By Astley Paston Cooper Ashhurst, A.B., M.D., F.A.C.S., Instructor in Surgery in the University of Pennsylvania. Cloth. Price, \$6. Pp. 1141, with 1039 illustrations. Philadelphia: Lea & Febiger, 1914.

The impression gained on a reading of this book is one of conservatism and practicability. Both bespeak the good judgment of the author, which is a comforting quality to the student or practitioner who depends on a text-book in any branch as a guide to study or for reference in his daily work. The principles of surgery are well and clearly laid down, and the diseases, accidents, operations and procedures which come largely within the skill and experience of the practitioner who does surgery are given a gratifying amount of attention, with concise but ample description. The more formidable surgical problems requiring the highest technic and knowledge are not neglected, but more details would perhaps be desired by many before attempting such work. Military surgery, the treatment of accidents and the suture of vessels and nerves are subjects detailed in a most satisfactory manner. In regard to fractures the author displays the conservatism taught by experience, no doubt, and early motion, massage and the open treatment are to be employed only with the greatest caution and in exceptional instances. The section on the arthritides is informing and practical. The special branches, orthopedics, gynecology, genito-urinary

surgery and the eye, ear, nose and throat have been treated only so far as they come within the province of the general surgeon. The illustrations, mostly from photographs, are abundant and appropriate to illustrate the text, and the book mechanically is well made.

THE HYPODERMIC SYRINGE. By George L. Servoss, M.D. Cloth. Price, \$2. Pp. 317. Newark, N. J.: Physicians Drug News Company, 1914.

The author has succeeded in producing a good-sized book on a small but important subject. In the short space of twenty pages, he has treated of the syringe and its uses. In enumerating the remedies employed by this method, the general class of bacterins obtains an entrance and the fable of the camel's nose is repeated. The bacterins drag in the subject of the etiology, pathology and treatment of infectious diseases, which occupy the remaining 300 pages, so that we have not merely a book on hypodermic medication but a compilation on the practice of medicine. A study of the structure of the book reveals some interesting facts. While the book is published by an independent firm, it is quite evident that the influence of a prominent manufacturer of serums and bacterins has determined its contents. The author has quoted freely, but a large part of his quotations are from "Working Bulletins" Nos. 1, 8, etc. There appears to be no editorial summarization of these varying statements, and the date of the material is different for the different preparations; for instance, on antidyenteric serum there is scarcely a reference to anything since 1902, while the section on antimeningitic serum refers to the recent epidemic in Texas in 1912, this bringing the article fairly well up to date. Naturally a book discussing the use of these remedies in the broad field of infectious diseases would require more thorough study than can be afforded by the mere clipping of quotations and statistics from various authorities. Such a book to be valuable must be the work of one fully equipped with theoretic knowledge and practical experience.

DIE NASEN-, RACHEN- UND OHRRERKRANKUNGEN DES KINDES IN DER TÄGLICHEN PRAXIS. Von Professor Dr. F. Göppert, Direktor der Universitäts-Kinderklinik zu Göttingen. Spezieller Teil, Enzyklopaedie der klinischen Medizin. Herausgegeben von L. Langstein, C. von Noorden and others. Paper. Price, 9 marks. Pp. 169, with 21 illustrations. Berlin: Julius Springer, 1914.

This small volume on the diseases of the nose, throat and ear in children is a special part of the "Enzyklopädie der klinischen Medizin." The subject-matter is divided into three parts, the first of which embraces the inflammatory diseases of the nose and nasopharynx, especially in their relation to the general system. The second part considers the independent local diseases of the nose and throat, while the third is devoted to the diseases of the middle ear and their results. It is a valuable contribution, especially in regard to the diagnosis and treatment of these conditions in infants, as too little attention in general is paid to these young patients. Of chief interest is the emphasis laid on the interrelationship of the local conditions with diseases that are constitutional in their nature.

ESSENTIALS IN BACTERIOLOGY. Being a Concise and Systematic Introduction to the Study of Bacteria and Allied Microorganisms. By M. V. Ball, M.D., Assisted by Paul G. Weston, M.D., Pathologist State Hospital for Insane at Warren, Pa. Saunders' Question Compend. Seventh Edition. Cloth. Price, \$1 net. Pp. 321, with 118 illustrations. Philadelphia: W. B. Saunders Company, 1913.

The author and editor of this little book propose an attempt "to reflect as faithfully as possible the present status of bacteriology without overstepping the limits set by the scope of a book intended primarily as an aid to students." The scope of the work and want of space have not permitted the consideration of theories and obsolete methods. Part 1 consists of chapters on general biologic considerations and technic of staining, culture, animal experiments, etc.; Part 2 of chapters on the special bacteriology of non-pathogenic and pathogenic bacteria. The appendix takes up yeasts, oidiums, molds, etc. A table at the end, arranged alphabetically by names of species, gives the chief characteristics of the principal bacteria, pathogenic and non-pathogenic.

Miscellany

Suicides and Newspaper Publicity

The probable influence of newspaper publicity of details regarding the nature and kind of substances used in connection with accidental or intentional poisoning is well shown by a compilation from the reports of the coroner of St. Louis for the years 1910 to 1914, inclusive.

The annual period covered by the latest report, April 1, 1913, to March 31, 1914, includes the time during which much unwarranted and in many respects misleading publicity was given to cases of bichlorid poisoning in the newspapers, and the comparative number of cases of poisoning by this agent in St. Louis is suggestive at least of the results that might have been expected. While in a general way the total number of cases of suicide by poisoning in 1913-1914 is comparable with the number occurring in previous years, there is a very marked increase in the number of cases due to the ingestion of mercuric chlorid.

The evident reduction in the number of cases of accidental poisoning from all causes leads one to suspect that newspaper publicity has had in this respect a beneficial influence in that it probably served to call attention to the desirability of safeguarding poisons in such a way that they could not readily be mistaken for other more or less harmless substances. The total absence from the reports for 1913-1914 of accidental cases of poisoning by mercuric chlorid also serves to discount the recent almost hysterical demand for special legislation to protect innocent persons from this deadly poison.

If any further argument were needed to induce newspapers to heed the frequently made request that they omit all mention of the details by which self-destruction was accomplished, it is shown by the accompanying compilation.

SUICIDE BY POISONING

	1910	1911	1912	1913	1914	Total
Arsenic	1	2	3	3	4	13

The figures given also suggest the desirability of telling the truth in regard to the action of corrosive poisons and the need for refraining from even an intimation that the use of any one poison or substance may lead to a sure and painless death.

In this connection it has been frequently pointed out that mentally unbalanced persons who in a fit of despondency might inflict on themselves serious damage would be likely

to be restrained by the dread of the unknown agony they may suffer from an attempt to do so, and because of this fact it cannot be too frequently emphasized that there are few modes of suicide more painful than death by means of any one of the many corrosive poisons that have been used in the past.

It might also be stated that only a limited number of the attempts at suicide by means of poisons are actually fatal and that in the majority of cases the ingestion of a poison leads to a painful, long drawn out convalescence and may, as in the case of bichlorid poisoning, involve permanent damage to vital organs, such as the kidneys, and thus materially influence the health and well-being of the individual for years to come.

Making Application of Available Knowledge

In an inaugural lecture on "The Necessity for the Practical Application of Available Knowledge," delivered before the class of the Veterinary Institute of the University of Melbourne in March, Dr. James W. Barrett cites two interesting points to illustrate his thesis. They concern infant mortality and the low standard of health of Australian women. Barrett says it is well ascertained in all countries that when the mean temperature of the air rises to 60 F., artificially-fed babies begin to die and that the death-rate, particularly in the first year, is high because of our failure to apply principles well known in prevention.

That the deaths are preventable in large part he asserts is proved by the experience of New Zealand, where the death-rate among infants in 1912 was about 51 per thousand as compared with 68 in Australia, 232 in Russia, 170 in the German Empire (1909) and 107 in the United Kingdom (1909). For the cities the comparison is still more striking, the rate in 1910 in St. Petersburg and Moscow being 280, Berlin 155 and London 103, while the rate in various Australian cities runs from 81 to 77, reaching the lowest point at Dunedin, New Zealand, where the rate was 38. The reduction in the death-rate in infants in New Zealand has been chiefly in gastro-enteritis, as is shown by the percentages of deaths from this cause, which in 1908 was 23.74, with a rapid reduction to 12.63 in 1912. While part of this reduction may be due to improvement in the milk-supply of New Zealand cities which, however, Barrett says is no better than that of Australian cities, or to the operation of the midwives act and the establishment of maternity homes, he believes it is due chiefly to "special and practical education."

In 1907 the Society for the Health of Women and Children was founded in New Zealand by Dr. Truby King, with the object of caring for the infant before birth and during the period of infancy by practical eugenics; to rear a strong and healthy race by constructive and not by restrictive means, and not to eliminate the unfit, but to prevent their production by aiding in the full development of the healthy. With the encouragement and assistance of Governor and Lady Plunkett, who appealed for assistance to the people, nurses were trained in the best methods of feeding and care of infants and sent throughout New Zealand to educate the women in the principles of child care and especially to urge breast-feeding. There are now twenty-seven of these "Plunkett nurses" and the cost is about \$20,000 a year, more than half of which is met by the government. The result, as Barrett says, has been achieved by applying scientific principles in the home.

On the second point, Barrett calls attention to the fact that while the general death-rate in Victoria (11.52 per thousand) and Queensland (10.65 per thousand) is low, it is notorious that the appearance of the women is not satisfactory. The men appear to enjoy excellent health, but in many instances the women appear anemic, neurasthenic and worn. This is commonly ascribed to the tropical climate, but this does not account for the health enjoyed by the men and the general low death-rate. The explanation Barrett finds in physiologic conditions and the wet-bulb temperature. Haldane has shown that work is rendered

impossible in a wet-bulb temperature of from 90 to 91 F., and that in a wet-bulb temperature over 78 F. a great deal of work could not be done with comfort. This applies whether the wet-bulb temperature is produced by a high dry-bulb and a low percentage of moisture, or by complete saturation with low dry-bulb. A plotting of the wet-bulb isotherms for Australia shows that it has a temperature below 70 F. wet-bulb in winter, and the greater part of it is below 75 F. wet-bulb in summer. Barrett says that this fact accounts for the good health enjoyed by the inhabitants in general and the low death-rate. It does not, however, account for the defective health of the women, which Barrett attributes in part at least to the high wet-bulb temperature of the kitchens and houses, as ascertained by actual tests in a number of cities and towns, a condition which should be easily remedied by the application of scientific knowledge at hand.

The whole fabric of modern curative medicine, Barrett believes, approaches the ridiculous because well-known scientific principles of prevention are not applied. He takes the view that it is more important to apply knowledge already existing than to seek for further knowledge, and that it is futile to enlarge the boundaries of knowledge by recon-dite research if no attempt is made to put the knowledge we have to practical use.

The Short Road to Success

We have, at various times, commented on the foreign opinion of American physicians and the brazen effrontery with which it is attempted to foist proprietary preparations on American physicians. More recently space has been given to a discussion of the so-called "painless childbirth" method of Freiburg, now being exploited by an American magazine. In view of this situation, the following comment by an American medical journal (the *Cleveland Medical Journal*) seems exceedingly appropriate:

"With the recent acknowledgment from *McClure's Magazine* (THE JOURNAL A. M. A., June 13, 1914, p. 1912) that their article, "Painless Childbirth," was technically correct and read by Professor Krönig and Doctor Gauss, we feel tempted, along with others, to lament the changes coming over many of the German medical men of to-day. The old German ideals of deep study, of verity and of thoroughness—what, may we ask, is becoming of them? Much of the German medical literature of to-day is flooded with superficial studies and absurd deductions on this, that and the other subject intended to attract the public eye. At Berlin and Vienna are arranged elaborate postgraduate courses of from one to four weeks or longer, principally shorter. They are ground out to your order, in English or German, at so many "simoleons" per minute and at the end, a much embossed, much begilded diploma will be duly handed out to the participant. We are glad to say that this does not apply to the work of many of the worthy professors in these great founts of medical knowledge, but sad to relate it is only too true of many of the courses offered. And what is even worse, Americans are the particular game and laughing stock of all too many of those privat-dozents, ausserordentlich professors, geheimrats, et cetera. American medicine has not yet recovered from the shock of Friedmann's Golden Fraud and we are pained to learn that Professor Krönig would also add his name to those men desiring dollars rather than wisdom and the honor of their fellow workers. We say this in spite of the recent denial from him as given in the *Lancet Clinic*. The German medical man has but to put a few titles before his name, appear in America and he feels himself called upon to burst out in public print to his heart's desire and his pockets overflowing—witness the example of a noted orthopedist a few years ago and just lately of an aurist. It is said that our remarkable antisyphilitic remedy, salvarsan, costs nine marks (about two dollars) a kilogram to manufacture and is sold to the public at the moderate price of nine thousand marks (about two thousand dollars) per kilogram. True, it is also said, that all the profits are turned over to the institute at Frankfurt; but what, might we ask, would happen if the Rockefeller or Pasteur Institute should adopt such tactics with so valuable a remedy? Think of the hundreds and hundreds of dispensary patients denied this drug because of its prohibitive cost. Is it possible that the German med-

ical man of to-day is, in his desire for material gain, forgetting the higher ideals of research, of teaching others and of healing the sick? There is much food for thought for his American colleagues and we deeply hope that medical Germany will take no chance to besmirch that high reputation of which she can be so justly proud."

Cleansing and Disinfection of Railroad Coaches

The usual carelessness of the traveling public and the close contact necessitated in railroad travel make the sanitation of railroad coaches an important problem in disease prevention. The railroads entering Asheville, N. C., a resort containing many sanatoriums for the care of tuberculous persons, have a method of disinfecting and cleaning their sleeping-cars and day coaches and their contents which is well devised and seems to be good enough to serve as a model. The procedure is described by A. D. Foster in *Public Health Reports*, March 27, 1914. Asheville is a division terminus and cars entering that place lie over for twelve hours, during which they are cleaned and disinfected. Sleeping-cars, day coaches and baggage-cars are switched to a special track, where the ventilators, windows and doors are tightly closed and the cars are fumigated with formaldehyd gas. The gas is generated in three galvanized iron pails for each car, each pail containing 500 c.c. commercial formaldehyd and 250 gm. potassium permanganate. In sleeping-cars all berths are taken down, and blankets, pillows and mattresses are opened and spread out so that the gas may have access to them. The car remains closed for about twelve hours. All carpets, upholstered seats and backs, blankets and pillows are then removed from the car and placed in the air and sun outside. Dust is removed from the removable seats, backs and carpets by means of compressed air, and similar cleansing of the interior of the car is performed. The floor of the car is then scrubbed with soap and hot water and the remainder of the woodwork is wiped with damp cloths. Drinking-water tanks and spittoons are removed, cleaned and scrubbed inside and out with brush and scouring-soap, rinsed with clean water and then sterilized with live steam. A small quantity of formaldehyd is placed in each spittoon. Once a month the tanks used for storing water for wash-rooms and water-closets are flushed and cleansed, and hoppers are cleansed with an acid solution. Woolen blankets are periodically shipped to special laundries where they are washed and combed. Day coaches and baggage-cars are cleaned and disinfected in practically the same way, and special attention is given to the space behind the steam-pipes which run alongside the coaches, a favorite place for expectation by passengers. This is scrubbed with hot water and soap and then scalded with live steam. The procedures described seem to be fairly effective methods of cleaning, and much in advance of those usually employed. For the proper protection of the public similar methods might properly be demanded everywhere.

Dual Responsibility of Physicians Connected with State Institutions

The supreme court in Vienna has recently decided that medical men connected with the municipal hospitals are liable for damages from malpractice the same as other practitioners elsewhere, as they are personally responsible for their actions in respect to patients. In their capacity of teachers, however, as professors in municipal and state institutions, they are responsible to the state, and they must be regarded as public officials to this extent. The case in which this decision was handed down was the appeal of a former official who had sued Prof. J. Hochenegg and three of his assistants for damages on account of the consequences of an operation on a furuncle. He asked 2,000 (about \$400) kronen and the difference between the salary he formerly received and the pension he was now getting. He lost his case at the first trial as Professor Haberda testified that the operation had been done strictly according to approved rules; and the lawyers pleaded that, in any event, the defendants, being physicians in the public hospital, were thus public officials and the case should be non-suited. The supreme court rejects this legal contention and remands the case for a new trial.

Medicolegal

No Damages for Mental Anguish from Physician's Failure to Attend Wife

(*Adams vs. Brosius* (Ore.), 139, Pac. R. 729)

The Supreme Court of Oregon affirms a judgment for the defendant, who was sued for \$50,000 damages for mental anguish asserted to have been suffered by the plaintiff on account of an alleged breach of contract by the defendant to attend the plaintiff's wife after she had met with an accident which produced a miscarriage. The court says that the doctrine that mental suffering accompanying personal injury or physical pain is always the subject of compensation is so firmly implanted in the jurisprudence of the several states of the Union as to become a legal maxim. In most cases, however, the mental anguish should be connected with the bodily injury and be fairly and reasonably the natural consequence that flows from it, and damages for prospective mental anguish are not recoverable as being too speculative. The sympathetic mental sufferings of the plaintiff on account of the suffering and pain of his wife, caused by the defendant's failure to observe his professional contract, were too remote and inconsequential to be actionable. It is the person who suffers the injuries proximately resulting from the wrong done, and such person alone, who is entitled to compensation, except in cases in which death results and the cause of action is made to survive to relatives, or personal representatives by virtue of the statute. Had death not claimed her for its victim, the plaintiff's wife possibly could have maintained an action against the defendant for the mental anguish and physical pain, if any, which she sustained as a result of the broken contract, but for the plaintiff no action was maintainable for purely mental distress.

Eugenics Law Constitutional

(*Peterson vs. Widule* (Wis.), 147 N. W. R. 966)

The Supreme Court of Wisconsin holds constitutional the eugenics law passed in that state in 1913. The court says, among other things, that the power of the state to control and regulate by reasonable laws the marriage relation, and to prevent the contracting of marriage by persons afflicted with loathsome or hereditary diseases which are liable either to be transmitted to the spouse or inherited by the offspring, or both, must, on principle, be regarded as undeniable. To state this proposition is to establish it. Society has a right to protect itself from extinction and its members from a fate worse than death.

Neither the legislative idea nor the legislative purpose in the passage of the present law can be a matter of serious doubt. The idea plainly was that transmission of the so-called venereal diseases by newly married men to their innocent wives was a tremendous evil, and the purpose just as plainly was to remedy that evil so far as possible by preventing the marriage of men who on examination were found to possess such diseases.

An argument was made that the law is void because the classification is unreasonable, arbitrary and discriminatory, in that it singles out men about to marry and makes a class of them; there being, as it was argued, no substantial differences which suggest the propriety of different legislative treatment between men who are about to marry and women who are about to marry. Theoretically the argument is strong. Women who marry and transmit a loathsome disease to their husbands do just as much harm as men who transmit such a disease to their wives; if women were in fact doing this thing as frequently or anywhere nearly as frequently as men, the argument could hardly be met. The medical evidence in the case, however, corroborates what the court supposes to be common knowledge, namely, that the great majority of women who marry are pure, while a considerable percentage of men have had illicit sexual relations before marriage, and consequently that the number of cases in

which newly married men transmit a venereal disease to their wives is vastly greater than the number of cases in which women transmit the disease to their newly married husbands. It follows that legislation directed against males alone for the purpose of preventing the transmission of venereal diseases is clearly within the police power and just as clearly is not discriminatory.

The court deems it clear that the act as passed was intended to cover only acquired venereal diseases as understood in medical science, and that the form of physician's certificate in the act is to be construed as covering only such diseases.

The act requires physical examination and "the application of the recognized clinical and laboratory tests of scientific search." It seems quite impossible to believe that it was seriously expected that the Wassermann test was to be considered a *sine qua non*. The court prefers to construe the words "recognized tests" as intended to refer to the tests recognized and used by the people who were to make them. This construction sustains the law, makes it reasonable, accomplishes its evident purpose, provides for a guard to marriage fully as effective in the vast majority of cases as the application of the Wassermann test. The court is inclined to the opinion that the fee of \$3 provided by the law is a very meager one; it should not, however, feel justified in holding the law unconstitutional on this ground.

Nor has the court been able to appreciate the contention that the law interferes in any respect with religious liberty.

Treatment Must be Tested by Principles and Practice of Particular School

(*State vs. Smith (Idaho)*, 138 Pac. R. 1107)

The Supreme Court of Idaho says that it seems to be a sound and reasonable rule and well established by the authorities that the treatment of a physician of one particular school is to be tested by the general principles and practices of his school and not by those of other schools, and that a physician or surgeon is bound to exercise such reasonable care and skill as is possessed and exercised by physicians and surgeons generally in good standing of the same system or school of practice or treatment in the locality and community of his practice, having due regard to the advanced state of the school or science of treatment at the time of such treatment. When a patient selects any one of the many schools of treatment and healing to serve him, he thereby accepts and adopts the kind of treatment common to that school or class, and the care, skill, and diligence with which he is treated, when questioned in a court of justice, should be tested by the evidence of those who are trained or skilled in that school or class.

The Sound Man.—Health is civic. Sound men will eliminate poverty and that of itself should make us all sanitarians. Sound men will learn to do without jails, recognizing that so-called criminals are properly speaking candidates either for educational reformatory or for a custodial hospital, and therefore again I turn gladly toward the dawn of the new health.—Edward T. Devine in the *Survey*.

8. **Acid-Fast Streptothrix.**—There is a fairly well-defined group of infections, the great majority of which are pulmonary, caused by weakly acid-fast branching mycelial growths (nocardia) which do not form ray-like granules. These cases clinically are not ordinarily distinguished from pulmonary tuberculosis. A case is cited by Davis in which the pulmonary lesions were very probably caused by such an organism. For the treatment of such cases, he says, potassium iodid should be given in large doses.

9. **Blood in Inanition.**—Ash found that the effects of starvation on the blood are: 1. There is a slight actual loss in hemoglobin, more marked during second ten days. 2. There are moderate fluctuations in water content, particularly during first half of period. 3. There is a decided rise in polymorphoneutrophils in the early days. 4. There is an increase in coagulability, especially after the first two weeks. 5. The blood as a whole is distinctly resistant to the effects of uncomplicated inanition, permitting of entire abstinence from food for long periods of time (at least thirty-one days) without deleterious consequences, as far as the blood is concerned.

10. **Pathologic Physiology of Circulation During Hemorrhage.**—Wiggers states that every hemorrhage, except one coming from a very large vessel, has a natural tendency to be checked long before the loss of blood becomes dangerous. The duration of bleeding depends not so much on the size of the vessels wounded as on the facility with which an efficient clot forms over the opening. When blood is shed, it begins to coagulate on the tissues at a distance from the opening. Having formed a point of adhesion to the tissues, it is added to by accretion until it reaches and covers the wound. The factors which determine the distance of the first clot formation and its development are, therefore, directly concerned with the duration of hemorrhage. Other factors being equal, the pressure at the arterial opening determines the distance that blood will be ejected before the force is sufficiently spent to permit the coagulum to form.

Wiggers has found that the maximal pressure in the systemic as well as in the pulmonary circuit is often entirely determined by the depth of respiration. It is quite possible that a drug which, in a normally breathing animal, increases the cardiac output and causes a rise in the average mean pressure may, nevertheless, by reducing the dyspnea during hemorrhage actually lessen the maximal pressure in the artery. The surface on which blood is shed determines the extent of its spread. Thus, the smooth surface on which the intestinal and uterine vessels rupture compares unfavorably with the reticular lung parenchyma and subcutaneous connective tissue. So, also, the spread may be limited by an ulceration or excavation.

The coagulation time directly influences the course of clot formation. The formation of clots may be retarded or prevented by muscular contractions of organs. The regular cardiac contraction, as a rule, absolutely prevents any clot formation over wounds of the heart and forms the only serious element in such wounds. The rhythmic peristalsis in the stomach and intestines are very unfavorable for clot formation and the induction of these movements in the intact abdomen by injections of epinephrin may possibly be sufficient to counterbalance any such favorable vascular influence. On the other hand, the only hemostatic value of atropin resides in its power to inhibit muscular movements and its use in conjunction with vascular agents such as epinephrin in hemorrhage from muscular organs is physiologically indicated especially, as the increasing percentage of carbon dioxid in the blood itself tends to increase the rhythmic contraction of organs. When hemorrhage terminates favorably by coagulation, the volume of blood returned to the right auricle increases with surprising rapidity. In consequence of the better venous supply and greater output of both ventricles, the pulse-pressure increases, for there is little alteration in the peripheral resistance and the increase in the volume elasticity coefficient remains an almost negligible factor. Both systolic and diastolic pressures thus gradually rise, owing to the augmented cardiac output.

All experimental observations made by the method described by Cope have indicated to Wiggers that vasoconstriction is a gradual process, starting while hemorrhage is still in progress and continuing after its cessation. If coagulation fails to occur, the time soon comes when the reduction in blood-volume exceeds the possibilities of lymph absorption, to such an extent that the mechanical function of the circulation cannot be efficiently carried out. The amplitude of cardiac contraction then decreases, largely because fluid is lacking to feed the pump. The reasons for saline infusion or blood-transfusion is obvious. Epinephrin also favors the rapidity of cardiac contraction in such cases and so improves the arterial pressure. The lack of oxygen in the blood soon changes the previous stimulation of the respiratory center to a depression. Slow and shallow breathing, occasionally marked by a deeper gasp, leads to complete cessation. The "pressor influence" of augmented breathing is removed and the blood-pressure falls rapidly. Asphyxial changes in the circulation terminate the case. The heart-beats are slow but of great amplitude and vigor, thus making a last attempt to elevate the pressure, which is partly successful but soon fails for want of oxygen.

11. Blood-Pressure in Pneumonia.—The blood-pressure curve does not suggest to Newburgh and Minot that there is a failure of the vasomotor center in pneumonia, nor are low systolic pressures "invariably of evil omen." The systolic pressure in the fatal cases tends to be higher than it is in the recoveries. Blood-pressure measurements in pneumonia cannot be used as a basis for treatment. Prognostic inferences based on the relation of the level of the systolic pressure curve to the pulse curve (Gibson's rule) are wrong more often than they are right. The rate of the pulse and not the level of the pressure is the chief factor in deciding whether the pressure will fall above or below the pulse. The pulse-pressure data secured by the authors are insufficient in number to justify conclusion.

12. Pneumococcus Infection and Lobar Pneumonia.—That the symptoms in pneumonia are probably due to toxic substances derived from the bacterial cells is the belief held by Cole. The outcome is dependent on the virulence of the organisms concerned and on the ability of the body, first to limit the local infection, and second, to prevent the invasion of the blood by the organisms, as on the latter the outcome of the disease mainly depends. Cole also believes that leukocytes probably play a part in the resistance, certainly as regards the local spread and probably also to some extent as regards the general infection. The most important part in prevention of the general infection is probably played by immune substances contained in the serum. Such substances are present in the serum of immunized animals. Pneumococci differ in regard to their immunologic reactions and on these they may be divided into several groups. In order to use immune serum effectively in treatment, as in prevention, Cole states, it is necessary to employ the serum effective against the group of organisms to which the special organism causing the infection belongs. Immune serums effective against two of the most important groups have been produced. This treatment has been carried out in a limited number of patients with promising results. It is probable that the methods of application of such serums will be improved, and it is possible that the method may be combined with other measures directed toward other factors which are important for the outcome. In any case, facts regarding the nature of the disease are being disclosed, and the outlook, at least for lessening the ravages of this dreadful disease, is encouraging.

13. Color-Index of Red Blood-Corpuscles.—The high color-index in pernicious anemia Meyer and Butterfield state is due to an increase in the oxyhemoglobin content of the erythrocytes. A quantitative study of the light absorption shows that oxyhemoglobin alone and no other derivative of hemoglobin is present in the blood of cases of pernicious anemia with a high color-index. The color-index of normal human blood varies within the narrow limits of 0.9 to 1.1. The average total hemoglobin concentration of normal defibrinated human blood is in the neighborhood of 16 gm. in 100 c.c. The color of the red blood-corpuscles is best explained by the principle of dichromatism as applied to the absorption spectrum of oxyhemoglobin.

14. Streptotrichosis and Its Differentiation from Tuberculosis.—Claypole holds that streptotrichosis is more common than generally supposed and frequently not differentiated from other infections; especially is it confused with tuberculosis. Clinical signs are not characteristic enough to determine the diagnosis accurately, therefore discharges—sputum, pus, etc.—should be carefully examined fresh in as large quantities as possible, and smears stained with carbolfuchsin and Gram stains. The amount of decolorization in the carbolfuchsin preparations should be varied so as to differentiate the less acid-fast types. Streptotrichins (glycerinated bouillon cultures, concentrated), made from the non-acid-fast mycelial and partly acid-fast bacillary organisms, give definite skin reactions on persons with frank infections, but do not show on controls (persons presumably non-infected) including cases of recognized tuberculosis. This either shows the infection to be less general than that due to the tubercle bacillus or else the reaction to be a less long-lasting one. Streptotrichosis and tuberculosis may exist in the same person at the same time, as evidenced by the appearance of both organisms in the sputum and both skin reactions. Gland and bone infections with streptotriches may be demonstrated by skin reactions as well as lung infections. This still further broadens the field for confusion between the tuberculosis and streptotrichoses.

15. Action and Therapeutic Effects of Leukocytic Extracts. Leukocytic substances possessing positive therapeutic value were procured by Archibald and Moore from leukocytes obtained directly from the blood of normal animals. These substances may be obtained in quantities which render them not only therapeutically practical but commercially possible,

conditions that can hardly be claimed for leukocytic extracts prepared from inflammatory leukocytes. The parenteral injection of leukocytic substances causes profound changes in the blood, producing a marked leukocytosis and marked changes in the individual leukocytes. As to the significance of these phenomena no opinion can be offered at this time. The authors hold that leukocytic extracts have not sufficient direct bactericidal powers to account for the profound changes produced following their parenteral introduction into an animal suffering from an infectious disease, and the beneficial results obtained are probably due to the fact that the extracts furnish elements which stimulate the fatigued or exhausted leukocytes, enabling them to carry on their function of phagocytosis and produce the changes incidental thereto.

16. **Bang's Micromethod for Determining Blood-Sugar with Bertrand's Method.**—Comparative experiments by Fitz show that the results obtained by the micromethod were not absolutely accurate if the results obtained by the Bertrand method are considered correct. In a series of forty-two determinations by both methods, however, in only two cases was there a difference of more than 0.03 gm. per 100 c.c. of blood. This means that, while the absolute error was large, the relative error was slight. The curve of blood-sugar determinations made from all the examinations was closely parallel. Hence for comparative and repeated studies in blood-sugar estimations the micromethod is admirable. Furthermore, since the amount of blood required to make the test is so small, and the technic so simple, the method affords an excellent clinical means for the estimation of blood-sugar.

30. **Disappearance of Ammonia from Blood.**—Even with the kidneys excluded from the circulation Jacobson found that ammonia injected into the blood is so rapidly removed from it that only a very slight excess is present five minutes after the injection. There is only a very slight difference between the normal and parathyroidectomized animal in the rate of disappearance of the ammonia from the blood.

35. **Preparation of Creatin and Creatinin from Urine.**—An interesting point in connection with the process described by Benedict is that it was originally tried as an expeditious method for the preparation of pure creatin. Instead of yielding creatin, perfectly pure creatinin was obtained. Following is the procedure: The recrystallized creatinin zinc chlorid (which should be finely powdered) is placed in a dry flask and treated with seven times its weight (by volume) of concentrated aqueous ammonia. The mixture is slightly warmed and gently agitated by shaking until a clear solution is obtained, care being taken to drive off no more ammonia during the warming than is necessary to obtain a clear solution. The flask is stoppered, allowed to cool, and then placed in an ice-box for an hour or more. Pure creatinin crystallizes out, and the first product obtained by this process should read 100 per cent. colorimetrically. The yield is from 60 to 80 per cent. of the theoretical. If the product is colored slightly yellow it may be recrystallized either from boiling alcohol, or by dissolving in five times its weight (by volume) of concentrated ammonia (warming enough to effect solution) and letting the solution stand in a cold place for some hours. Recrystallization is usually unnecessary. The product is perfectly pure, and may be used as a standard. Benedict adds that creatin is not converted at all to creatinin by warming with concentrated ammonia. So it would appear that this latter solution is perhaps the only aqueous solution in which either creatin or creatinin may be dissolved without any change from one into the other.

36. **Estimation of Creatin.**—The procedure for the determination of creatin in urine devised by Benedict is as follows: Such a volume of urine as will contain between 7 and 12 mg. of total creatinin is introduced into a small flask or beaker and from 10 to 20 c.c. of normal hydrochloric acid are added, together with a pinch or two of powdered or granulated lead. The mixture is boiled over a free flame as slowly or as rapidly as may be desired until very nearly down to dryness, when the heating should be continued to dryness either on a water bath, or very easily by simply holding the vessel in the hand and heating carefully for a moment or two. The residue should best stand on a water bath for a few minutes until most of the excess of hydrochloric acid gas has been expelled, after which it is dissolved in about 10 c.c. of hot water and the solution rinsed quantitatively through a plug of cotton or glass wool (to remove all metallic lead) into a 500 c.c. volumetric flask. Twenty to 25 c.c. of saturated picric acid are added, and about 7 to 8 c.c. of 10 per cent. sodium hydroxid solution

which contains 5 per cent. of Rochelle salt. The flask is filled to the mark at the end of five minutes and read as usual.

39. **Synthesis of Hippuric Acid.**—Lewis states that in man after the administration of from 6 to 10 gr. of sodium benzoate elimination as hippuric acid takes place very rapidly, 85 to 90 per cent. of the ingested benzoate being excreted in from five to six hours. The rate of elimination of hippuric acid after the administration of sodium benzoate is only slightly less rapid than after the administration of hippuric acid. After benzoate ingestion, the urine collected during the first six months, the period during which the greater part of the hippuric acid is being excreted, has a lower urea plus ammonia content than in a normal control period, indicating that hippuric acid nitrogen is derived at the expense of the nitrogen normally eliminated as urea.

40. **Formation of Glucose from Dioxycetone.**—Four experiments were performed by Ringer and Frankel in which dioxycetone was administered subcutaneously to phlorizinized dogs. In every case a rise in the glucose elimination followed. The "extra" glucose in one experiment corresponded to an amount of glucose which would arise if all of the carbon of dioxycetone were converted into glucose. The effect of dioxycetone on acidosis is decidedly anti-ketogenetic in three of the four experiments. Dioxycetone was found in the urine in unchanged form in only one of the four experiments. In that case the urine reduced Fehling's solution in the cold and reacted positively with the Miller-Taylor reagent. In none of the other experiments did dioxycetone appear in the urine.

42. **Metabolic Relationships of Acetone Substances.**—The behavior of acetoacetic acid, *l*- and *dl*-oxybutyric acids and butyric acid, in the metabolism was studied by Marriott by means of incubation experiments on hashed organs, and by parenteral introduction into normal and phlorizinized dogs and young pigs. The analytic results obtained from individual organs, the circulating blood, and the urines have led to the following conclusions: 1. Acetoacetic acid can be readily converted into *dl*-oxybutyric acid in the organism, but the reverse change is difficult, and probably not accomplished under normal conditions. 2. The dextro component of *dl*-oxybutyric acid can be utilized even by the diabetic organism, and this is the explanation of the appearance only of *l*-oxybutyric acid in diabetic urines. 3. The normal path of fatty acid catabolism is as follows: Fatty acid—(butyric acid?)—acetoacetic acid—*d*-oxybutyric acid (readily burned) *l*-oxybutyric acid (difficultly burned).

44. **Estimation of Albumin in Urine.**—The principle of the turbidity method described by Kober for the determination of proteins in milk and in digestion mixtures as used by Folin and Denis for the determination of albumin in the urine is as follows: To about 75 c.c. of water in each of two 100 c.c. volumetric flasks is added 5 c.c. of a 25 per cent. solution of sulphosalicylic acid. A second method, the gravimetric determination of albumin in urine is described as follows: Ten cubic centimeters of urine are pipetted into an ordinary conical centrifuge tube which has been previously weighed. To this urine is then added 1 c.c. of 5 per cent. acetic acid and the tube allowed to stand for fifteen minutes in a beaker of boiling water. At the end of this time the tube is removed from the water bath and centrifuged for a few minutes. The supernatant liquid is then poured off, the precipitate in the tube is stirred up with about 10 c.c. of boiling 0.5 per cent. acetic acid and again centrifuged. The supernatant liquid is then again poured off and the precipitate in the tube again washed, this time with 50 per cent. alcohol. After centrifuging and pouring off the supernatant liquid for a third time the tube is placed for two hours in an air bath at 100 to 110 F., then cooled in a desiccator and weighed.

47. **Volumetric Estimation of Sulphur in Urine.**—This method has for its basis, the estimation of benzidin in the precipitate of benzidin sulphate, rather than the sulphuric acid.

49. **Iodin Content of Tuberculous Tissues.**—Tuberculous tissue derived from animals to which no iodine preparation has been knowingly administered Lewis and Krauss state may contain amounts of iodine very appreciably higher than normal control tissue of the same animal. While it is quite probable that tuberculous tissue in animals treated with iodine products may store up iodine, this has been by no means clearly shown in any experiments so far reported. The highest figures for the tuberculous tissue of untreated animals in their experience may equal the highest figures of those reported by others as evidence for the localization in the tissue of iodine intentionally administered.

72. **Organism of Small-pox, Chicken-pox and Vaccinia.**—Greeley noted that in fluid vaccine virus, by hanging-drop observation, one might frequently see large numbers of motile bodies and that the same, no matter what vaccine virus was used, could be obtained from the vesicles of the inoculated. They stained with Giemsa, Neisser and Unna stains. The organism is evidently a sporothrix. In the form of multiplying spores (thus in vaccine virus and in all papules, vesicles and pustules) it is spherical, its diameter varying in the neighborhood of from 0.3 to 0.6 microns. When actively multiplying all present a nucleus which takes the usual anilin dyes with varying facility. A frequent form is a pneumococcus-like couplet which, when stained by Neisser's method, shows a colorless refractile capsule with slightly pink lining, of figure 8 shape, and, within, a blue-stained nucleus in each section—the two nuclei often connected by a bridge of pink whose intensity varies inversely with the distance between nuclei. When these nuclei are nearest together (cell just dividing) the pink is very intense. In all skin lesions the spores multiply, as stated, developing into branching masses whose units are the same as in the figure 8 shape described. These conglomerations often show,

projecting from the extremity of a branch, highly refractile, non-stain-taking spores, borne on the end of a little stem. Several are sometimes seen at the end of the same branch, and often two connected in dumb-bell form. These spores when detached are actively motile, the stem becoming the single flagellum possessed. Muir's or Van Ermengem's flagellum staining method will demonstrate. Greeley states that these spore bodies are evidently the "*Cytoryctes variolae*" described by Councilman and others. They divide and give rise in skin lesion and in culture to the formations aforementioned.

Under certain cultural conditions (which are being studied and will be reported later) a full mycelial growth develops with hyphae and terminal spores. Greeley suggests that this is probably what occurs on the mucous membranes (nasal for instance) in the beginning of these diseases, and the spores, penetrating into the blood-vessels, are wafted to all parts of the system, landing in the skin capillaries in which conditions of lower temperature and more light, perhaps, favor further proliferation. In this connection we should remember how the eruption favors the face and hands.

The organism is gram positive—nucleus purple, capsule sometimes light pink—and when stained with carbol-fuchsin is slightly resistant to decolorization with dilute acid, nucleus resists 10 per cent. acetic well. Organisms will not produce a macroscopic growth on any known solid media, aerobically or under hydrogen. It readily passes Berkefeld laboratory filter No. 5. Cultivation has been successful enough to permit the second generation derived from a specimen of the market's vaccine virus to give one take out of two human inoculations. An apparently identical organism has been obtained from the vesicles of twenty-five cases of successful vaccination, from a like number of cases of undoubted chicken-pox, and from five cases of recognized and unquestionable small-pox.

81. Cardiac Headache.—The prime indication in the treatment of a headache or its analogue, a facial neuralgia from a weak or weakened heart, Kolipinski says, is to strengthen, support, or, if possible, to restore it to normal. This can alone be done where the many acts in life which overtax this heart and weaken it still more, are persistently and intelligently avoided. Where eyestrain is found glasses must be used. If obesity is present the weight must be brought to normal. If tobacco is used it must be given up. This applies in every case of cigarette smoking and to this petty and enfeebling vice when practiced by females. The weakened heart of chronic nicotine poisoning is a counterpart or double of organic myocardial weakness, and it is impossible to separate or distinguish one morbid state from the other until the tobacco poisoning is eliminated.

Rest of the body must be practised as a daily system. One who works must retire at 9 or 10 o'clock and arise at 7. For one incapable of work or who lives retired, the afternoon rest must never be omitted. Afternoon sleep indicates accurately and absolutely a marked degree of exhaustion. Sleep or drowsiness in the afternoon does not occur when the subject possesses more muscle tone and strength, i. e., a stronger heart. Where the afternoon rest is not taken, where the patient is engaged in business or work, the daily hours of lying down should still be as long as possible. Twelve continuous hours of rest are not as helpful as the same number of hours of the afternoon and night. The afternoon rest, which is an adaptation of the tropical siesta, a physiologic habit, is of great benefit in the treatment of all heart diseases not in an acute or grave condition.

Medicinal treatment is essential to cure a chronic headache. There are two remedies of similar action which will accomplish this. Digitalis is the first. It should be given in a single dose, repeated in one or two days, and continued for months and years. The powder of the leaf, its tincture, fluid extract or infusion may be prescribed. Rest and digitalis cure cardiac headache. Even improvement or occasional cure results, but the obstinacy of this afflicting malady is so inveterate that the patient does not receive fair and full attention where they are not combined. Now and again digitalis fails or must be given with sodium iodid to regulate the pulmonic circulation. Where digitalis does not help, the substitute for the time is strophanthus; with arterial sclerosis, aortic valve defects, pulmonary engorgements, strophanthus and sodium iodid. Strophanthus in a few instances replaces digitalis. Sometimes digitalis must be suspended and strophanthus given instead until the heart again becomes susceptible to digitalis. Strophanthus acts best with laxative or purgative drugs. In fact, the strophanthus action, with free movements of the bowels and vomiting, is no disadvantage when it is given for cardiac asthma, lung edema or similar states of other viscera. An efficient remedy for a severe paroxysm of cardiac headache will be found in 2 grains of caffein citrate in a teaspoonful of aromatic elixir every fifteen or thirty minutes till relief is felt.

83. Obstetric Complications.—The first report Applegate makes is one cesarean section including hysterectomy, under spinal anesthesia, eighteen hours after complete rupture of the uterus at term. The second report is of a patient with fibromyxomatous degeneration of the chorion associated with an anomalous fetus, partially macerated, with hare-lip, cleft palate, ankylosed shoulder and elbow joints, and ascites. The diagnosis of placenta praevia had been made by the family physician, and it proved to be the marginal type. The third case was one of multiple subserous fibroids of the uterus, complicating pregnancy; hysterectomy was performed at the third month of gestation. Under ether inhalation anesthesia, the patient left the hospital in three weeks in good condition. The fourth case was one of placenta praevia centralis at the beginning of the eighth month. Cesarean section was performed under spinal anesthesia.

85. Eosinophilia in Chorea.—Leopold studied the blood in twenty cases of chorea. Of the twenty cases a distinct eosinophilia varying from 4 to 16 per cent. was present in ten (50 per cent.). There were nine patients showing recurring attacks of chorea. The number of attacks varied from two to five. Eosinophilia was found in six of the nine patients (66½ per cent.). Four of the nine patients showing recurring attacks of chorea had only a single recurrence. Of these four cases, eosinophilia (4 per cent.) was present in one. The three remaining cases did not show eosinophilia. In one the diagnosis was very doubtful. The five remaining cases showed from three to five distinct recurrences; eosinophilia ranging from 6 to 16 per cent. was present in every case.

There were eleven cases in which the blood was studied during or after the first attack. Three of these were not considered, because in one the diagnosis was extremely

doubtful, and in the other two there was no chorea perceptible at the time the blood examination was made, although the patients had apparently recovered from true chorea. None of the three showed eosinophilia. Of the eight remaining cases studied in the first attack, eosinophilia, ranging from 4 to 6 per cent., was present in four (50 per cent.). In none were the eosinophils higher than 6 per cent., whereas in the recurring cases 13, 15 and 16 per cent. were observed.

91. Eczema in Infancy.—The eczema of infancy and early childhood which, Freeman states, is occasionally due to external irritation is usually caused by gastro-enteric derangement and must be attacked primarily by correcting that derangement. The food should be cut down to the caloric requirements, the ration should be balanced and digestion aided. Stewed fruits and cream should be prohibited. The parts affected should be kept well covered with non-irritating applications.

94. Vaginal Discharge.—In ordinary cases of cervicitis (not of gonorrheal origin), the application of strong solutions of 20 per cent. and 30 per cent. solution of nitrate of silver, tincture of iodine or pyroligneous acid, after first clearing out the mucus from the cervical canal by an alkaline solution, McMorro says, will sometimes effect a cure, but healing by medicament is rare—only in cases in which the necks of the glands are wide open and an application can get in. In the majority of cases local applications provoke new formations of stratified epithelium, which may cover or bridge over the mouths of the glands, causing a false or pseudo healing. The glands are still active and secreting mucus; generally two weeks later, rupture of the glands takes place and cervical discharge commences.

When an operation is inadvisable, an effective method of treating these bad cervical infections, is by the use of actual cautery, heated to a bright red heat introduced well into the cervical canal, making five or six deep radial strokes at each treatment, not attempting to burn out all the diseased tissue at one sitting; this treatment should be repeated in three weeks and a sterile strip of gauze is left in the vagina to take care of possible hemorrhage. McMorro employed this plan of cauterization with good results, noticing a marked improvement and lessening of the discharge after each application. These cauterizations do not even call for a local anesthetic except in weak and nervous women, then it is well to inject a few drops of a 4 per cent. solution of cocaine into the cervix; the patient is able to leave the office afterward with very little discomfort.

The best method of treating most of these infections in McMorro's experience consists in dilating the cervix and with a sharp curet, strongly applied to the diseased cervical glands, eradicate them from the dense matrix by which they are surrounded; this method at least lays the mouths of the glands wide open and drains them. This treatment is generally curative and satisfactory. A trachelorrhaphy will often give relief if done thoroughly and enough of cervical tissue cut away, so that these glands are mostly removed at the same time. In extremely obstinate cases a circular amputation of the cervix will effect a permanent cure.

110. Treatment of Pellagra.—The general care of the pellagrin is summarized by Dyer as follows: Insist on cheerful surroundings; have the patient adopt the motto "Look up" and adhere to it. Establish a morale from the beginning by an optimistic view of the prognosis. Warn the patient of a long time treatment, of relapses and of the need of proper care and treatment between the attacks. Keep out of the sunlight. Spend the day between sun up and sun down on the shady side of the house, with the light obscured. Also keep out of the kitchen and away from over-heating occupations. Keep the patients out of bed, so long as this is possible. Do not let them go to bed except to rest, or when the symptoms of the disease compel.

When the acute symptoms are controlled, reduce the quinin hydrobromate to 2 grains three times a day and give general tonics, as the glycerophosphates, lactophosphates, iron and manganese compounds. Arsenic is permissible and serviceable. Dyer usually gives the sodium arsenite with other tonics, as:

	gm.	or c.c.	
R. Liquor sodii arsenitis	20		gtt. iii
Tinct. nucis vomicae	1		gtt. xv
Tinct. gentianae comp.	1	or	gtt. xv
Tinct. cinchona comp.	1		gtt. xv
Syr. pruni virginianis	q. s.	ad	3 i

M. et Sig.: In water after meals.

Blaud's compound pills are also useful. The improvement in appetite, strength and desire to take gentle exercise are signs of improvement. No better criterion, however, can be found than the gradual gain in weight. As the loss in weight is a constant factor in the syndromes of pellagra, so the obverse is more than casual in its importance with relation to a return to normal.

The most important period of treatment in most cases of pellagra is during the usual seasons of attack or in the months of cold weather. Every effort should be made to bring the patient up to normal of resistance. The physician should see the patient often enough to maintain a psychologic relation which will permit control. The dietetic care, the medicinal treatment (tonics, regulations of functions, etc.) should be systematic. The weight should be recorded regularly so as to see what normal may be maintained. As the warm season approaches any loss of balance can be noted and met. Often a change of climate for these patients treated already during the first attack will obviate a recurrence.

8. Problems in Cardiac Physiology.—It is shown by Kent that there exist in the heart, in the neighborhood of the auriculoventricular groove on the left side of the organ, neuromuscular structures whose constituents are partly nervous and partly muscular, and these have connections with the nervous structures of the groove and with the muscular tissue of auricle and of ventricle. There exists also in the right lateral wall of the heart a mass of hitherto undescribed nodal tissue. In association with this mass there exists at least one muscular path between auricle and ventricle along which impulses can pass, and which is able to keep the chambers in physiologic association even when the auriculoventricular bundle has been cut. Experimental results have been obtained by Kent which completely bear out the anatomic fact of the existence of an additional muscular path between auricle and ventricle.

In the exposed heart of the mammal the bundle has been cut and electrocardiograms have been taken subsequently. These showed that the rhythm between auricle and ventricle persisted. In the beating heart of the mammal a thin knife was passed through the right ventricle, near the groove, and brought out in such a way as to sever completely the auricles from the ventricles with the exception of a strip of tissue at the right side of the heart. Under these conditions it was found that beats arising spontaneously in the right auricle pass through to the ventricle, and evoke ventricular beats, and, after the heart has ceased to beat spontaneously, beats excited artificially in the auricle still pass through to the ventricle and give rise to ventricular beats.

Since under these conditions the only tissue connecting the auricle to the ventricle is the strip at the right side of the heart, and the histologic part of the inquiry has already shown that an anatomic connection exists in this situation, it is impossible to avoid the conclusion that in this right lateral auriculoventricular junction there exists a muscular path capable of transmitting impulses and of coordinating the action of the chambers of the heart. Further, since, as has been shown, the muscular path is completed by the interposition of a mass of nodal tissue, through which the impulses must pass, it is clear that the conditions here are similar to those found in the case of the auriculoventricular bundle, and that the auriculoventricular pause may be explained on similar lines—that is, as being due to the passage of the impulse over tissue modified histologically and physiologically, with a resulting delay in conduction.

9. Endemic and Exophthalmic Goiter.—The object of Farrant's paper is to record observations made on eighty-five cases of goiter (exclusive of simple hyperthyroidism) between

1909 and 1914 as to the relationship between toxemias and diseases of the thyroid; to prove that in cases in which the thyroid is diseased the causatory micro-organism or toxemia can be determined; to show that in this way not only can diseases of the thyroid be cured, but also prevented. Endemic goiter, according to Farrant, is caused by the toxins from the atypical forms of *B. coli*. The mutants are usually conveyed by water. They become indigenous in the intestine, and different mutants of *B. coli* are to be found in the feces of cases of endemic goiter. The mutants are but rarely present in the feces of normal individuals or in the feces of individuals goiterous from other causes. It is possible to conceive circumstances which place the *B. coli* under abnormal conditions in the intestine itself, and lead to mutation and the temporary appearance of mutants in the feces of normal individuals. The mutants set up an apyrexial toxemia, which stimulates the thyroid, so leading to a colloid hyperplasia and eventually to enlargement of the gland. The whole process can be imitated in the laboratory, and endemic goiter induced in guinea-pigs by feeding with small doses of the mutants.

The supervention of a fresh toxemia while the gland is in a hyperactive state causes a complete hyperplasia, with absorption of colloid and signs of hyperthyroidism up to a condition of exophthalmic goiter. This is dependent on the intensity and duration of the fresh toxemia. Endemic goiter is preventable by the avoidance of water contamination and by the sterilization of contaminated water. It can be cured by the administration of intestinal antiseptics, the gland returns to normal, providing no degeneration has taken place. The gland as a whole involutes to normal, but the adenomata or cysts are left. A condition similar to endemic goiter can be caused by other toxemias capable of inducing a colloid hyperplasia.

Exophthalmic goiter, Farrant claims, is due to a combination of toxemias of an intensity sufficient to cause a hyperplasia with absorption of the colloid material. One acts during a period sufficient to give rise to a complete hyperplasia associated perhaps with slightly marked signs of hyperthyroidism without necessarily any glandular enlargement. The supervention of another infection stimulates the gland, which usually enlarges, and the signs of hyperthyroidism become very evident; the case develops into one of typical exophthalmic goiter. A nervous shock may lead to the diagnosis by suddenly bringing into evidence the symptoms of hyperthyroidism, especially those connected with the nervous system.

The severity and duration of exophthalmic goiter is dependent on the intensity and duration of the toxemias. If they be of short duration the disease will disappear in a few months. Exophthalmic goiter can be prevented by the detection of the early cases of hyperthyroidism and the consequent removal of the basal toxemia. Exophthalmic goiter can be cured if the causatory agents be removed before degeneration has occurred either in the gland or in those organs that are affected by the hypersecretion.

When degeneration has taken place in the thyroid removal of the toxemias causes involution to take place only in the hypertrophied portion; the adenomata and cysts are left. These require appropriate surgical treatment, as they to a certain extent keep up the symptoms of thyroid excess. Surgical treatment without removal of the cause is followed by recurrence unless so much of the gland substance has been removed that hypersecretion is impossible. Degeneration in the other organs partially recovers after involution of the thyroid; appropriate treatment is necessary for those that remain. Acute cases of exophthalmic goiter may present themselves in which surgical treatment is the only means of saving them, though the risk of death under the anesthetic perhaps precludes operation.

11. Radical Cure of Inguinal Hernia.—O'Connor employs a long incision, extending from the level of the pubic spine to a point about one inch below and internal to the anterior superior iliac spine. The superficial epigastric and superior external pubic vessels are seized with forceps, divided between

and ligated, and the aponeurosis of the external oblique thoroughly exposed. The intercolumnar fibers of the external ring are then snipped with scissors and with the handle of the scalpel the aponeurosis is split, parallel to its fibers, to the upper limit of the incision. The divided aponeurotic "leaves" are next seized on each side by pressure forceps, which act as tractors, and considerably facilitate the thorough separation of the former, by blunt dissector, from the underlying structures. Free and isolate the cord, and separate, incise and remove the hernial sac, and suture the opening flush with the peritoneal cavity. This completed, the cord is raised up and placed well out of range of injury behind the two tractor forceps attached to the edge of the internal leaf of the divided aponeurosis. The external leaf is drawn firmly downward and outward until the inner shelf of Poupart's ligament comes well into view.

Taking this exposed shelf as level, a curved hernia needle is passed from without inward right through the reflected aponeurosis—the lower one embracing in transit some fibers of Gimbernat's ligament—passed across the floor of Hesselbach's triangle, and made to emerge through the substance of the conjoint tendon. The needle is now threaded with strong catgut and withdrawn. The unthreaded needle is again similarly introduced about half an inch above the former and a mattress suture completed. Three more similar ones are inserted through the above level and sufficient room is left at the upper angle for the passage of the cord. When these four sutures are tied the inner shelf of Poupart's ligament is firmly approximated to the conjoint tendon. Hesselbach's triangle is completely obliterated. Finally, the two aponeurotic leaves are united by a continuous catgut suture, and in doing this insert the point of the needle deep enough to catch hold of underlying muscle in order that no intermuscular dead space may be left. The cord is left, as in Halsted's operation, superficial to the external oblique.

- 18 Working of Midwives Act (England, 1902). F. H. Champneys.
19 "Sustentacular Apparatus of Female Genital Canal. V. Bonney.

19. Displacements of Genital Canal.—Bonney urges that the terms "prolapse of the uterus" and "falling of the womb" are misnomers and should be replaced by others expressive of the nature of the displacement. The uterus not only takes no part in the production of "prolapse," but actually resists the attempt of the vaginal culdesac to turn inside out. Inversion of the uterus and ectropion of the cervix are the uterine homologues of vaginal inversion and eversion. In the treatment of the displacements of the genital canal the nature of the displacement in each individual case should be determined accurately. The indiscriminate application of a particular method of treatment should be abandoned in favor of measures founded on the nature of the displacement in each case.

The absence in the past of a scientific basis to operative treatment has led to much bad surgery. Thus ventrofixation is still performed by some for vaginal eversion—a perfectly useless proceeding—while cases of pure vaginal inversion are still more often thus treated, although the resistance of the intact broad ligaments often makes it impossible to fix the uterus high enough to exercise efficient traction on the vaginal vault. Combined laxity of the middle and lower supporting groups is frequently dealt with by repairing the pelvic floor alone, with the natural result that the patient presently returns complaining that "womb falls again." Mistakes such as these will not occur when it is generally recognized that in the treatment of the results of sustentacular relaxation accurate knowledge of the fault that lies behind the deformity is the first essential for success.

29 English Medicine and Surgery in Fourteenth Century. D. Power.

21. Case of Retrocolic Hernia.—Fisher's case came to notice in the dissecting-room. The subject was a man, aged 57, whose death was due to senile degeneration of the heart. On opening the abdomen a broad apron-like fold was seen stretching across the greater part of the right side of the abdomen. Further examination showed that the fold of peritoneum was the anterior wall of a hernial sac. On the left side it was attached to the "hepatic" flexure of the colon, ascending colon and cecum. Superiorly it was attached to the lower border of the first part of the duodenum and became adherent to the right edge of the great omentum. On the right side it bulged somewhat and became continuous with the peritoneum over the right kidney and iliac fossa. Anteriorly it presented a free edge which was by no means tense, and it was devoid of any vessel. The lower free edge ran in the interspinous plane and was attached laterally to the peritoneum over the right psoas muscle, and internally to the posterior surface of the appendix and meso-appendix. The anterior wall of the sac occupied the lower half of epigastric region in its right two-thirds, right two-thirds of umbilical region, and the right lumbar and hypochondriac regions, and the upper third of the right iliac and hypogastric regions.

The cecum was rotated and kinked, so that the posterior surface looked directly forward and the anterior surface was in contact with and partly hid from view the ascending colon. The appendix occupied the upper left quadrant of the hypogastric region. The transverse colon consisted of two limbs, a descending and an ascending. The descending ran from the hepatic flexure following the left lateral plane as far as the brim of the pelvis; the ascending limb passing upward and outward in the left iliac and lumbar region to splenic flexures. The kink in the transverse colon lay over the brim of the pelvis and was connected to the anterior surface of the cecum. The great omentum had the usual attachments but was pushed over into the left side of the abdomen and ended in a long pointed process. The liver and stomach were normal in their position.

On opening the sac it was seen to extend upward beneath the right lobe of the liver, and it was seen that the condition was due to a developmental abnormality. On the floor of the sac was the root of the mesentery, attached along an oblique line stretching from the junction of the first and second parts of the duodenum downward and to the left to the termination of the ileum. Its length was about 6 inches. Some five feet of small intestine, presenting a perfectly normal appearance, were also found in the sac. The second part of the duodenum, which was also in the floor of the sac, had a continuation of the mesentery attached to its left side, but was adherent behind to the posterior abdominal wall in a fairly normal way. The third part of the duodenum was freely movable, having a common mesentery with small intestine from which it was indistinguishable. It was not crossed by the superior mesenteric artery, neither was there any trace of a duodenojejunal flexure. The whole length of the small intestine was only 9½ feet.

22. Hemorrhagic Typhoid.—In the first of these cases, during the course of the fever, there developed an extensive

purpuric eruption, which was followed by a generalized bleeding from the mucous membranes, viz., the tongue, gums, bladder and intestines. In the second case hematemesis occurred while the fever was at its height. This happened on three occasions, together with bleeding from the bowel. The third case was one of intestinal hemorrhage complicating typhoid and ending in recovery.

26. Femoral Hernia Treated by Bone Transplantation.—Greene's patient, a male, aged 57 years, had a double femoral hernia of about fourteen years' duration. That on the right side was very large and caused great inconvenience; that on the left was smaller, but had recurred a year after an operation previously undertaken. The right-sided swelling was reducible, and the whole hand could be introduced into the ring. The sac was exposed by means of a transverse incision, the contents reduced, and the neck ligatured in the ordinary manner. About 2 inches of the eleventh rib were then excised subperiosteally and the bone was split into two pieces through the cancellous tissue. The femoral wound was then widely retracted and the bone grafts were introduced into pockets made in the periosteum at the back of the pubic bone. There was no trouble in fixing them, and Poupart's ligament was then drawn down to the pectineus fascia, leaving a firm bone plate on its abdominal aspect. The left hernia was dealt with by the ordinary method. The wounds healed soundly and the bone transplant can be felt firmly in position. The shadow of the transplanted bone can be seen in the roentgenogram.

28. Carcinoma of Liver in Child.—The points of interest in Freeman's case were the primary malignant growth of a carcinomatous nature in a child of only 3 years of age, the absence of all secondary deposits, and until the end was quite near the comparative absence of pain, tenderness, or of decided dyspepsia or anorexia.

Archives Générales de Chirurgie, Paris

- 30 *Cancer of the Testicle. J. Sakaguchi. Commenced in No. 5.
31 *Cancer of Large Intestine in the Young. J. Baur and P. Bertein.
32 Intestinal Pneumatosis. (Kystes gazeux de l'intestin.) P. Maurice.

30. Cancer of the Testicle.—This article is based on study of museum specimens and a few clinical cases—a total of thirty-two cases of cancer of the testicle. In one case the testicle was the seat of both a cancer and a tuberculous process with no direct connection between the lesions. In four cases there was a history of local trauma. As a rule the cancer does not cause pain or enlargement of the testicle and the chance for operating is often lost before the malignant disease is recognized. The ages of the patients ranged from 2 to 60 or more, one man of 26 succumbing to metastases which are common with cancer of the testicle. Most of the patients were between 30 and 50.

31. Cancer of the Large Intestine in the Young.—Baur and Bertein have encountered 2 cases in young soldiers and have compiled 19 other cases in persons under 20. Nine were in the cecum or colon but 12 were at the sigmoid flexure. In 2 cases the patients were under 10; in 11, under 20, and in 7, under 25; all were males except 7 and one monster with a congenital cancer in the colon. In all but 2 cases only seven or eight months elapsed between the first signs of trouble and death; in the others, two and four years. Pain is usually the first symptom to attract attention. It may be localized far from the site of the lesion and it may occur in paroxysms. In one case melena was the first sign of trouble, in 3 cases sudden complete ileus and in another ascites. Three of the patients were cured for the time being in the 5 cases in which the growth was resected.

39 *Pellagra. L. Sambon.
40 Spontaneous Healing of Bilateral Renal Processes. J. Castaigne.

34. Toxic Action of Enlarged Prostate.—Bazy protests against calling the removal of the enlarged prostate a "prostatectomy" as the prostate itself is not removed but only the proliferating glandular tissue, the adenoma, obstructing the passage. The operation should be called rather "prostatic adenectomy." The prostatic tumors seem to have a directly toxic action in addition to the mechanical obstruction. He reports two typical cases in which the general health showed remarkable and permanent improvement after the operation although there had been no retention of urine previously, as the bladder had been constantly drained and sterilized. He has been very successful with his operations on the prostate, and ascribes this to his practice of tamponing the cavity after removal of the exuberant gland tissue, packing the tampon around a large retention catheter. A large tube in the bladder wound permits continuous irrigation with saline, a drop at a time, the fluid escaping through the catheter. The tube is removed the fourth day and the bladder sutured.

39. Pellagra.—Sambon traces the history of pellagra from a description of the disease by Pliny down to the present and shows that it prevailed in those early days in Spain, Italy, France, etc., the foci known then being still in the pellagra zones. He quotes Osler's statement in 1906 that pellagra does not exist in the United States and Babcock's discovery of it in 1906; in 1912 it had been encountered in thirty-two states and 30,000 cases had been recorded. The disease was not known in Great Britain until Sambon in 1912 started out to look for it, and in a few weeks found over 20 cases and now knows of 100, showing that it is endemic in England, Scotland, Ireland, Wales and the Shetland Islands. The disease there is typical pellagra, exactly like the pellagra he has studied so closely in Italy and elsewhere. Pellagra, like malaria, has certain defined zones, and they do not include cities. All the evidence is against direct contagion; not an instance is known of transmission of the disease to others. He adds that he took a pellagrin girl from Italy to England five years ago and she has served as cook in his family since, and has been cured for about two years. Persons who go to reside in a pellagra focus inevitably contract the disease and usually in the first year, while others who work in the pellagra zone in the winter but leave it in the spring escape the disease. Another analogy with malaria is that in the pellagra zones the children are affected; infants escape it until they are old enough to be taken into the fields. He has encountered it in a 3-months babe; one family of five all developed pellagra fifteen days after moving into a pellagra focus. He has encountered cases recently in various parts of France. Sambon incriminates two species of gnats as the transmitters of pellagra, the *Simulium* and the *Ceratopogoninus*.

42 *Exclusion of the Pylorus by Suture for Gastroduodenal Ulcer. P. Frangopoulos.
43 Hernia of the Bladder: Three Cases. (Hernie de la vessie.) A. Glückstahl.

41. Colectomy for Cancer.—Viannay believes that colectomy completed in one stage is the operation of choice for cancer

if the patient's condition permits it. Of course there are cases in which the two-stage operation is to be preferred—if the patient's general condition is very poor or the colon is firmly fixed by adhesions. In all other cases he opens the abdomen, removes the tumor with free excision of surrounding tissues, sutures the bowel at once and closes the abdomen without drainage. He reports in detail twelve cases on which he has operated for cancer of the intestine. In five of them he performed the one-stage operation without a death; in the other seven the two-stage operation was executed, with three deaths.

42. Exclusion of the Pylorus by Suture.—Frangopoulos discusses the numerous methods of excluding the pylorus and suggests one of his own by simple suture which he has used successfully in two cases. After the usual aseptic technic he irrigates the stomach with a solution of naphthol in water, makes an opening in the lesser and greater omenta, passes an angiotribe through the opening and crushes the pylorus. He then passes a gauze compress through to the opening, passes his index finger over that back of the pylorus and inserts the sutures with a fine curved needle. The insertion of the sutures takes only two or three minutes. The omentum is then sutured over the pylorus. There was no rise of temperature or other sign of infection in either of his cases. The method has the advantage of extreme simplicity and rapidity of execution.

44 *Bean in Bronchus. (Corps étrangers des bronches.) J. Sallès.

44. Foreign Bodies in the Bronchi.—Sallès has found records of 55 cases in which an organic foreign body slipped into the air passages and in 19 cases the foreign body was a bean; in 8 cases a fruit stone; in 10 a pea or coffee bean. The mortality averaged about 50 per cent. and it is probable that an unsuspected foreign body has been the cause of many more fatalities recorded under other headings. In nearly every instance the organic foreign body was "swallowed the wrong way" while the child was laughing hard or coughing, and he insists that parents should be impressively warned of the danger of allowing children to play with dry beans or peas, or laugh when eating them. It is safer to mash beans when served to small children. When the organic foreign body is hard, it should be got out without a moment's delay, but temporizing may be justified with a bean or pea cooked soft as long as there are no signs of bronchitis. Metal foreign bodies are tolerated better than the organic, as a rule, and roentgenoscopy locates them, which is not possible with a bean or similar organic foreign body. Turning the child upside down has little hope of success and he protests vigorously against this dangerous measure unless the foreign body is small, hard and smooth, like a glass bead. With the aid of prompt bronchoscopy the mortality has declined from 50 to 13 per cent. (1909) and Killian reported in 1913 a mortality of only 8.7 per cent.

- 48 *Lactation in Wet-Nurses. C. Brodsky.
49 *Multiple Sclerosis in Boy of 12. C. Stamm.
50 *Acute Nephritis in Infants. F. Frank.

48. Lactation in Wet-Nurses.—Brodsky gives in forty-five tables the various details in regard to milk production in seventeen women nursing several babes at once and having the residuum carefully drawn afterward. One of the women, a primipara of 25, did not seem to have enough milk for

her own child the first three weeks, but she was given four to nurse and later six, and by the fortieth day she yielded 1,465 c.c. milk and by the seventieth over 4,000 and kept this up for 230 days, once reaching 5,400. By the end of the year she was still giving 2,050 c.c. He thinks her daily average, 3,520 c.c. for 339 days, has established a new record, at least for Switzerland. The yield of milk increases when several babies take the breast and it increases still more when the gland is pumped practically dry afterward.

49. Multiple Sclerosis in Boy of 12.—Stamm says that the negative Wassermann, the changes in the fundus, and the improvement under bed rest and eight intragluteal injections of a preparation of thiosinamin all testify that the presumptive diagnosis of multiple sclerosis was correct. None of the symptoms has returned during the eight months to date; speech and gait are normal and the child seems healthy except for a certain sluggishness in the pupil reaction and slightly exaggerated knee and Achilles reflexes.

50. Acute Nephritis in Infants.—Frank gives the details of 22 fatal cases and comments on the frequency of the hemorrhagic tendency, which was marked in 9. In 12 cases the trouble seemed to be of blood-borne origin; in 7 it was an ascending pyelonephritis. Some focus of infection elsewhere was evident in every case; several foci in some. In 30 cases of otitis media in infants there was also nephritis in 5; regressive changes in the kidney in 10, and in 4 there were hemorrhages plus inflammation in the bladder. Frank emphasizes the significance of the frequent participation of the urinary passages in gastro-intestinal disease in infants, something of the kind being evident in the great majority of his cases.

56 *Technic for Induced Pneumothorax. C. Saugman.
57 Favorable Results with "Old" Tuberculin. (150 Tuberkulinfälle.) Busch.

56. Induced Pneumothorax.—Saugman devotes nearly a hundred pages to this practical study of artificial pneumothorax as he has applied it in the course of seven years to more than 200 patients. He gives an illustrated description of the technic and insists on the necessity for keeping the patient in bed until the pneumothorax has been effectually induced, or at least until there is no longer any temperature. Until the lung is adequately compressed by the induced pneumothorax the patient should stay in the sanatorium or hospital; only under exceptional circumstances should the pneumothorax be undertaken in a private residence. The main reason for this is on account of danger from the extra work thrown on the other lung. Saugman says that during the six months' period of "active" pneumothorax treatment the patient should be in a sanatorium equipped for this treatment, and in case of complications a one or two years' stay is advisable. This is his practice at the Vejlfjord Sanatorium in his charge in Denmark. He does not consent to the patient's leaving before this unless he feels quite well, when all the manifestations of the active lung disease have long disappeared and their place been taken by the signs of an extensive pneumothorax—the "clinical cure" of the Italians—and the patient can live under favorable conditions at home, and the injections do not have to be made oftener than three or four weeks.

When all these conditions are realized he consents to the patient leaving and gradually taking up some light occupation. Many of his patients were able to return to their business in six or twelve months and soon felt fully capable.

Of course they lived strictly hygienic lives and under constant medical supervision. The "active" treatment stage once past, all that is necessary afterward is to maintain the pneumothorax. This is the special aim of the International Pneumothorax Association, so that wherever the patient may happen to be at the time he can get his injection by a uniform technic when the gas needs replenishing. Saugman urges practitioners in general to take a course in this technic so that they will be able to make the injection properly when a patient applies to them for the purpose if there is no trained specialist available. Among the points to be borne in mind is that a change from one altitude to another modifies the pressure so that the gas may have to be replenished at once. When it is not replenished at the proper time it may prove impossible to induce an effectual pneumothorax again.

- 63 Primary Syphilitic Lesion from Practice of Holding Pencil between the Lips. O. Heinemann.

58. Atypical Gout.—Goldscheider calls gout atypical when there are no attacks of pain but the blood and urate deposits, etc., are fully typical of true gout. In the last two years he has encountered 271 cases of tophi without the gouty attacks. The tophi were in front of the knee in 159, in the shoulder in 122, and in the sacrum or ear in 22 cases each. He mentions only 11 cases of tophi in the fingers. A gritting noise in one or more joints was evident in 112 cases, with or without tophi, and in some of the cases tophi developed later in the joints involved. In his experience with true paroxysmal gout this gritting in the joint was evident in 21.9 per cent. of the men and 58.3 per cent. of the women. In the cases free from tophi, it occurred in 5.4 per cent. of the men and 33.3 per cent. of the women. It was most prevalent among those who took least exercise.

62. Roentgenography of Sphenoidal Sinus from Within.—Freystadt introduces directly into the epipharynx the film on a flat flame.

- 65 Pharmaceutical Advertising Matter on Card-Catalogue System. (Vereinheitlichung der Arzneimittel-Reklame.) M. Roch.

64. Combination Treatment of Varices.—Matti resects the varicose veins a little at a time, and induces thrombosis in the stretches between by injecting phenol. By proceeding slowly and gradually in this way, he avoids extensive resection of the saphenous vein. The patches of extremely dilated veins are resected but the rest are spared and they merely shrivel and become plugged by the reaction to the injected phenol. Seven cases are reported in which this comparatively mild but extremely effectual combination treatment was applied.

66. Treatment of Threatening Conditions in Pleurisy.—Grober says that when conditions demand relief from the effusion at once, we can generally assume that the lung is not adherent to the pleura and can thus venture to use a simple puncture needle instead of a trocar. To regulate the pressure and thus avoid doing harm by abrupt changes of pressure, he runs the needle into a fish bladder, when a suitable apparatus is not at hand. The fish bladder gives to the pressure and does not permit air to be sucked into the needle. The same purpose is accomplished by a tube on the end of the needle, the other end submerged in a vessel with salt solution. By raising and lowering the vessel the pressure in the needle can be regulated and the tube clamped with a clothes-pin.

He advises withdrawal of the effusion even when it is of moderate amount if there is fever, indicating a septic course, or if the effusion is bilateral. When there is fever it seems wise to rinse out the pleural cavity thoroughly with some mild disinfectant even if the effusion is apparently limpid. He declares that every practitioner should familiarize himself with the correct technic for thus flushing the pleural cavity through two minute openings or more extensive openings to clean up an empyema. If the effusion is tinged with blood, too much of the fluid should not be evacuated at a time or the hemorrhage may recur. With cancer, the effusion always rapidly collected again in his cases. Mishaps do not occur so often after puncture now as formerly, as we do not wait until it is the last resource. After each puncture the patient must recline for a time and a camphor injection may be useful. Even with all precautions we are still unable to ward off positively danger of embolism of the pulmonary artery.

Pain is best combated by cupping; the blood thus drawn relieves the congestion and pressure below, but he has never witnessed any benefit from strapping the chest with plaster. An important indirect means of influencing the effusion is to apply all possible measures to aid in the throwing off of fluids; calomel aids usefully in this, both by way of the bowels and the kidneys (0.3 gm. three times a day at most). He has always found that this had a very powerful diuretic action; by the second or third day, up to 8 or 10 liters of urine may be voided. Of course the calomel can not be used in this way unless the kidneys are sound; any tendency to nephritis would be much aggravated by it. Another effectual means of throwing off fluids, he adds, is to chew chewing gum vigorously, spitting out all the saliva, keeping this up all day long. He says of sodium salicylate as a diuretic, that its injurious action on the sound kidneys is only transient and should not deter from its use in appropriate cases.

67. Retrogression of Symptoms after Removal of Growths Causing Compression in the Central Nervous System.—Rothmann's extensive report of experiments on animals concludes with a most encouraging view as to the remarkable effects that may be realized by systematic, persevering exercise to restore function. Restitution of functioning is materially promoted and hastened by appropriate exercises. Even dogs paralyzed from removal of the brain, soon learned to follow the moving chair with their hind legs when their front legs were placed on the chair. The phylogenetic older functions were lost last under the affection in the central nervous system, and these were regained first. This point should be borne in mind in starting and carrying on the course of exercises. His research fails to sustain von Monakow's conception of diaschisis.

- 88 *Operative Treatment of Bronchiectasia. A. Wydler.
- 89 *Gastric Ulcers Remote from the Pylorus. Faulhaber and E. von Redwitz.

85. Gastric Crises and Vagotomy.—Exner and Schwarzmunn report experiences which show that the vagus forms part of the reflex arcs which are involved in the production of the gastric crises in tabes, and that by severing the vagus nerve the reflex arcs are broken up and hence there can be no more of the gastric crises. They have operated in 14 cases on this assumption and 7 of the patients were freed completely from the gastric crises, 2 others materially improved, and no benefit was apparent in 2. None seemed to be injured by the operation; the crises were not aggravated in any instance. In the others the operation is of quite recent date. Four other surgeons have done vagotomy for gastric crises in a total of 6 cases, curing 3 of the patients; no benefit in 1, and aggravation of the crises in 1. This is a total of 50 per cent. cured; 10 per cent. improved, and 15 per cent. quite recent operations. Resection of the posterior dorsal roots, as applied by Foerster and three others, now has a record of 45 or 48 per cent. cured of 145 patients, with from 11 to 23 per cent. mortality. The vagotomy is comparatively simple; 1 cm. is resected from the vagus on each side. The difference in the outcome may depend on the anatomic conditions encountered; in 9 of their 14 patients the vagus was still a trunk nerve under the diaphragm; in 3 others it branched before piercing the diaphragm, and in one case only some of the branches were accessible. The details and outcome are tabulated for each case.

86. Tuberculous Stenosis of the Pylorus.—Pfanner reports a case of this kind in a young man successfully operated on. He had a chronic apical affection and severe stenosis at the pylorus developed suddenly, without premonitory symptoms, suggesting a gastric ulcer. The tuberculous process was in the upper duodenum and involved the pylorus and this entire stretch was resected. The apical process subsided also and the young man seems now, six months later, to be on the road to perfect health.

87. Operative Treatment of Exophthalmic Goiter.—Glaserfeld has compiled from the literature 2,032 operations on the thyroid, with a mortality of 5.4 per cent., but the percentage is growing constantly less with better technic and better appreciation of the contra-indications. In 534 cases in which the operation was done for exophthalmic goiter, 349 of the patients regard themselves as cured (65.36 per cent.) and 88 (16.48 per cent.) very much, and 41 considerably improved. The operation was a failure in only 31 and there has been recurrence in 25. In later series the cured and improved reach 73 to 90 per cent. The tachycardia and tremor subsided after the operation in 80 per cent.; the psychoses in nearly all cases; the diarrhea and amenorrhea in all, while the protruding eyeballs subsided into normal place in 53.7 per cent. of all the cases. The only means to estimate the actual value of operative treatment, he reiterates, is to have internists and neurologists make systematic after-examinations from a uniform standpoint, such as is outlined in a question-blank which is given in full. He sent it to fifty leading internists and neurologists in Germany and Austria, and fourteen were returned filled out, but evidently there has

been no systematic study of the ultimate condition in these operative cases. Glaserfeld was unable to find any evidence that these patients operated on for exophthalmic goiter were rendered any more susceptible to other diseases thereafter.

All agree that operative treatment should not be considered until medical treatment has been given a thorough trial and shown that it is inadequate to cope with the disease. The slightest sign that any one of the symptoms is growing worse during medical treatment may be accepted as a call for an operation even in the mild cases. This requires that Basedow patients must be under constant medical supervision; when this is the case there is little chance that the best time for the operation will pass unobserved.

88. Operative Treatment of Bronchiectasia.—Wydler's experience in the case reported shows that it is better to proceed at once to resect the lobe of the lung involved without wasting time on resection of ribs and ligation of the pulmonary branches. Little if any benefit was realized from four operations on the ribs but after resection of the lobe of the lung almost a complete cure followed. The patient was a young man with bilateral congenital bronchiectasia; the sputum was so offensive that he was unable to hold any job. As the bronchiectasia affects the opposite lobe to some extent, the cure was not absolutely complete.

89. Gastric Ulcer at a Distance from the Pylorus.—This study of 52 cases treated by gastro-enterostomy or resection shows that the ultimate outcome is far better with radical, circular resection. When there is extreme hyperacidity it might be wiser to remove even more than this of the stomach mucosa; the Billroth II might be better in this case. Mere gastro-enterostomy is liable to be followed by various complications. Danger of malignant degeneration is not so imminent as generally supposed; there have been no signs of cancer in the seventeen cases of "callous" ulcer operated on from two to five and a half years ago. The long duration and the periodicity of the gastric disturbances are special features of these cases of "pylorus-remote" tumors, and roentgenoscopy clinches the diagnosis.

- 98 *Deforming Arthritis. (Die deformierende Gelenkentzündung im Lichte neuerer Forschungen.) L. v. Stubenrauch. Commenced in 27.

92. Parasitic Epigastric Monster.—Marchand gives an illustrated description of a young man who has a twin monstrosity growing from his stomach region. Born in 1884 of Italian parents at Buenos Aires, J. J. Libbera is now a young man of average weight and size, apparently normal except for the headless male twin growing from his stomach region, about the size of a child of 3. The mother bore another pair of united twins among her thirteen children and one uncle was badly deformed.

96. Excrecences of Gonorrheal Origin.—Klingmüller describes six cases in which there was proliferation of tissue on the perineum or anus in women with a gonorrheal process in the urethra, cervix or rectum. In one case there were also condylomas. The excrecences were something like a cock's comb and some were painful but none bled. They were excised in most of the cases.

97. Diagnosis of Brain Tumor.—A bright, active and ambitious boy of 11 in a few weeks became lazy and slovenly, and began to steal money and bury it. Nine months after this change in character had been noticed, other symptoms of a brain tumor developed and a sarcoma was found in the left

cerebellum. The accompanying hydrocephalus had modified the corpus callosum to such an extent that pronounced left apraxia resulted, diverting attention away from the true seat of the lesion, particularly as the tumor was of such soft tissue that for a long time it caused no symptoms of pressure. In a second case the symptoms pointed unmistakably to a cerebellar tumor. Except for the changes in the gait, they all came on with a stormy onset, with fever, two weeks before the attempt at operative treatment. The sarcoma was not reached and the girl of 15 died the next day.

98. **Deforming Arthritis.**—Stubenrauch emphasizes that the light cast on deforming arthritis by recent research calls for treatment based on static, mechanical and functional principles, as he describes in detail. A history of joint trouble should be borne in mind in selecting a trade or business; in continuing at work, unless the joint can be spared, the process is liable to keep on a progressive course. Early recognition of the joint process is thus indispensable to ward off serious mischief and deformity, and modern methods of diagnosis render this possible, especially when the pain and other subjective and objective findings are correlated with the weight-bearing task and the roentgenograms. Gentle exercise of the joint wards off ankylosis and should be supplemented by every possible measure to stimulate return of normal conditions in the various tissues of the joint. The process with deforming arthritis starts in the joint cartilage, not in the bones, and it is these changes in the cartilage which impair its elasticity and throw the joint out of gear, entailing the deformity. Recent microscopic study by G. Pommer of Innsbruck has confirmed the combination of functional and anatomic factors in the production of deforming arthritis.

104. **Thread and Wire Extension from Skin.**—Klapp applies extension in severe cases of ischemic paralysis of the arm after fracture by a set of double silk threads each passed through the pulp of a finger and all drawn and tied together a foot beyond the tips of the fingers. A 5-pound weight is then suspended for twelve or fourteen days from the knot thus formed. The skin never tears out, the fracture heals and contracture is warded off in both arm and hand. He often has found this technic extremely useful after operations on the hand and arm. A thread can be passed in the same way through the skin of the heel; he found this of great advantage in a recent case after operating on a babe for congenital deformity of the leg. For adults he prefers a wire passed slanting through the heel on each side, the ends drawn out at the bottom of the heel. He applied this technic in eleven cases during the Balkan campaign and found it as effectual as nail extension. The wire or thread must be drawn through the soft parts exactly in the direction in which traction is to be exerted. Otherwise the pressure from the wire cutting into the tissue will cause necrosis.

- 106 *Early Sign of Pregnancy. (Ein häufiges Frühzeichen der Schwangerschaft.) A. Labhardt.
- 107 Abdominal Intrapertitoneal Correction of Retroflexion of the Uterus. W. Rindfleisch.

106. **Early Sign of Pregnancy.**—Labhardt says that the dregs-of-wine discoloration of the mucosa of the vagina characteristic of pregnancy can be detected very early in a transverse strip extending to right and left between the mouth of the urethra and the base of the hymen, closer to the latter than to the urethra. This broad strip of livid tint can be detected usually long before the discoloration is evident elsewhere in the vagina. It is a sign of the venous hyperemia set up by the fact of the pregnancy, and is liable to be encountered with a tumor in the vicinity. But as a rule it is a simple and useful early sign of pregnancy. The discoloration occurs usually most pronounced in women who have already borne children.

- 110 Nascent Iodin Local Treatment of Uterus. (Airolo ed acqua ossigenata nella medicazione della cavita uterina.) A. Cerioli.

109. **Arrest of Inflammation by Analgesics.**—Silvestri systematically kept four patients with acute cerebrospinal meningitis under the influence of a general anesthetic, hoping thus to allay the local inflammation. The ordinary measures, ice to the head, etc., were applied as usual, but these were supplemented by calcium bromid by the mouth and in enemas, and chloral alternating with morphin. The secret of success is to begin with the analgesics at the very outset of the inflammation and keep it thus under control. He applied the method also in a case of severe polyneuritis with herpes zoster and in several cases of convulsions in young and old. The dosage varied with the case, but he gave the meningitis patients up to 8 or 12 gm. of calcium bromid a day. He found the results very encouraging, confirming the inhibiting action on inflammation of shutting off sensory impulses.

111. **Hemoglobinuria with Hookworm Disease.**—Manzi reports the case of a girl of 14 with a puzzling syndrome of pains and other disturbances in the bladder, dark-colored vomit and urine and extreme pallor but no tube casts. She tired easily and became irritable and melancholy. The discovery that a neighbor had recently returned from a long stay in a hookworm country finally gave the clue to the trouble, and under a course of thymol treatment ova were found in the stools and recovery followed. There did not seem to be intestinal hemorrhage from the mechanical action of the helminths; the blood-corpuscles were evidently being destroyed by the toxin. The eosinophilia and leukocytosis were probably part of the defensive reaction. The temperature kept persistently above normal during the hemoglobinuria stage.

130. **Ambard's Formula in Determination of the Renal Function.**—Kholzoff has been giving a thorough trial to Ambard's formula for estimating the work of the kidneys by the proportion between the urea in the blood and in the urine. This "uremic constant" was described in detail in THE JOURNAL, March 7, 1914, page 813. Kholzoff thinks that the total amount of urea and chlorids eliminated by the kidneys during the twenty-four hours is of greater import than the percentage in urine or blood. At the same time he lauds the Ambard index as accurate and reliable, giving a better idea of the renal function than any other method. He says the method is not reliable for determining the function of each kidney separately, because the technic of collecting urine from each kidney is not perfect. Yet it is highly important to collect the whole amount of urine without any losses. Therefore, this method can have only a limited use, as, for instance, for the purpose of determining the function of both kidneys, or when there is but one kidney from congenital deformity or from disease.

131. **Serous Meningitis with Brain Tumors.**—This according to Minz is a frequent occurrence with brain tumors, not only before trephining and removal of the tumor but even after a successful operation. There is liable to be enormous

accumulation of the cerebrospinal fluid, especially with tumors of the posterior cranial fossa or corpora quadrigemina. This causes symptoms of meningism or the symptoms of actual meningitis may occasionally become exacerbated (severe headache, vertigo, vomiting, etc.). Minz recommends puncture of the subarachnoid space, which he has successfully performed in a case of a glioma of the corpora quadrigemina, of a tumor of the middle skull cavity, two cases of successfully removed cerebellar cysts, and in one case of psammoma of the occipital lobe of the brain.

132. **Operative Treatment of Epilepsy.**—According to Korotneff and Minz, surgical treatment of so-called genuine epilepsy is not justified or only when the patient demands same. Temporary improvement may be obtained in some cases. True cortical epilepsy, including the traumatic due to some lesion of a perfectly healthy brain, may occasionally yield to an operation, but a success can not be guaranteed in every case. Trephining is alone justified.

133. **Rabies.**—Oushakoff declares on the basis of two cases of hydrophobia that even insignificant skin lesions caused by a rabid animal may cause hydrophobia, and that a dog bite can be held harmless only when the animal has been kept under observation by a veterinary physician during one week, at least, and found healthy. Otherwise the suspected person must be treated in a Pasteur institute. In the presence of symptoms of hydrophobia, accelerated pulse and general excitement, the surrounding persons must be warned in regard to the possibility of infection, and, if necessary all should be given prophylactic Pasteur treatment which proves as a rule very efficient. The young women were not actually bitten in his two cases. Both died of the rabies; it was not recognized at first. He says that pain at the point of infection may be a clue to an early diagnosis.

137. **Aneurysm with Acute Endocarditis.**—Lindbom reports a case each of aneurysm in splenic or in iliac artery as a complication of acute endocarditis. His review of the literature on the latter shows that embolic aneurysms are comparatively common with acute endocarditis. They develop mostly in the arteries of the abdomen or limbs and may rupture. The symptoms of internal hemorrhage then dominate the clinical picture or there may be merely sudden violent pain with a pulsating enlargement of the artery. This was the most frequent type in the 18 cases he has found in the literature. Operative removal of the stretch of the vessel involved has given good results in several cases and should be recommended on account of the dangers from rupture. The tendency to embolism persists however and new aneurysms may be formed. Three clinicians have reported cases in which the aneurysm developed in the coronary arteries.

- 138 *Roentgenotherapy of Uterine Hemorrhages and Fibromas. H. J. Panner and S. Kjaergaard. Concluded in No. 29.

138. **The Roentgen Ray for Uterine Hemorrhage and Fibromas.**—Panner and Kjaergaard review some of the recent literature on this subject and tabulate their own experiences. They indicate that one can rely on curing uterine hemorrhage with the Roentgen rays when the ovaries are responsible for the hemorrhage. The functioning of the ovaries can be checked by the Roentgen exposures and the myomas themselves generally shrink under them too. The treatment in these cases need not be intensive. Of his ten patients with uterine hemorrhage without a tumor, all but one were cured by the exposures and in the eight fibroma cases the tumor subsided materially in all but one. The great drawback of roentgenotherapy is that under it a cancer might be allowed to slip past the operable-curable stage.

THE PATHOLOGIC PHYSIOLOGY OF UTERINE BLEEDING *

EMIL NOVAK, A.B., M.D.
BALTIMORE

The study of uterine bleeding is given a peculiar interest by the fact that the uterus is the only organ in the body from which a periodic hemorrhage occurs as a physiologic phenomenon. The logical point of departure in the investigation of pathologic uterine hemorrhage, therefore, would seem to be a study of the normal type of uterine bleeding, that is, menstruation. Even a superficial familiarity with the enormous literature of the subject, however, will convince one that the problem is rarely approached in this fundamental way. In the study of all the menstrual disorders the tendency has been to lose sight of the fact that there are many links in the menstrual chain, and to emphasize some one factor at the expense of others, which may be equally important. As regards the explanation of uterine bleeding, it is the anatomic point of view which has in recent years received most attention. This is perhaps not surprising when we consider that up to very recent times our knowledge of the menstrual process has been much more highly developed along anatomic than along physiologic lines, and that structural alterations in an organ are far easier to demonstrate than aberrations of function. More and more, however, we are beginning to realize that the uterus is only a keyboard on which many variations are played by a complicated menstrual mechanism whose ramifications extend far beyond the confines of the pelvic cavity. Not only the uterus, but all the other constituent parts of the menstrual apparatus as well are subject to disturbances of one form or another, and hence none of them should be overlooked in the investigation of uterine hemorrhage of obscure causation.

At the outset it may be conceded that in the majority of instances the cause of uterine bleeding is anatomic, in some cases very frankly so. For example, uterine cancer is a perfectly obvious cause of bleeding from the uterus, just as rectal cancer may cause bleeding from the bowel. The same clear relationship is seen in the case of a few other lesions, more especially those of neoplastic type. We may thus distinguish, first of all, a type of uterine hemorrhage clearly due to well-defined and easily demonstrable causes in one part or another of the uterus. There would be hemorrhage from lesions of this type even

though there were no such thing as menstruation to cause a periodic flare-up in the pelvis.

A second group of cases may be distinguished in which a lesion of some sort exists either in the uterus or in the adnexa, but in which hemorrhage would probably not occur were it not for the extra congestion which each menstruation brings with it. A tubal inflammatory mass or an ovarian neoplasm might not in itself be capable of producing hemorrhage, but it frequently exaggerates the menstrual hyperemia, and hemorrhage is the result. When metrorrhagia or intermenstrual bleeding occurs, it would seem at first sight to indicate a direct effect of the lesion itself on the pelvic circulation. This, however, does not necessarily follow, for it is possible, as some have contended, that in many of these cases the disturbance of the menstrual mechanism is much more fundamental, involving the function of the ovary itself.

Finally, there is a third group of cases in which uterine hemorrhage occurs in the entire absence of any clearly demonstrable disease in any of the pelvic organs. I use the expression "clearly demonstrable" advisedly, for numerous efforts have been made to explain the bleeding in these cases along anatomic lines. For many years it was the endometrium which constituted the target for the diagnostic acumen of gynecologic pathologists. The work of Hitschmann and Adler,¹ confirmed by many others,² has done much to clarify our knowledge of the part played by the endometrium in the menstrual process. Except in certain rather exaggerated conditions, such as polypoid endometritis, it is difficult to fix on the endometrium any great measure of responsibility as a cause of uterine bleeding. Many of the supposed abnormalities of the endometrium are perhaps the results rather than the causes of the menstrual disturbances, for we are apt to forget that the hypertrophic changes of the premenstrual period represent the reaction to periodic hyperemia of a very labile tissue—and a tissue made more labile by constant repetition of the process over many years, or, from an evolutionary point of view, over many ages. Abnormalities of the menstrual phenomenon, either in rhythm or in intensity, may thus be reflected in the endometrium, which plays a purely passive part in the process. Furthermore, since the endometrium is always "on edge," it may undergo hypertrophic changes as a reaction to hyperemia other than that associated with menstruation.

In view of our inability to fix the responsibility for uterine bleeding entirely on the endometrium, it is not surprising that the search for a local cause has gone

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

1. Hitschmann and Adler: *Monatsch. f. Geburtsh. u. Gynäk.*, 1908, xxvii, 1.

2. Gardner, W. S., and Novak, Emil: *The Endometrium and Some of Its Variations*, *THE JOURNAL A. M. A.*, Oct. 9, 1909, p. 1155.

deeper into the uterus. It was Scanzoni, in 1861, who first directed attention to the importance of the mesometrium in this connection. Although receiving little attention for many years, the subject has in recent years been again brought to the forefront by the work of Theilhaber³ and others. It is not within my province to discuss the various theories which have been put forth—the “insufficiencia uteri” of Theilhaber, the “metrorrhagia myopathica” of Anspach, etc. There can be little doubt that the myometrium, like the endometrium, is responsible for a certain number of cases of uterine hemorrhage, but the proportion is probably not so large as to throw any great light on the mechanism of uterine hemorrhage in general.

Even less important, to my mind, is the rôle played by disease of the blood-vessels in the production of bleeding from the uterus. Much importance is attributed to this factor by Pankow,⁴ Slocum⁵ and others. There are many objections to such a view, especially to the explanation which many offer that the bleeding is the result of an actual rupture of the blood-vessels—an “apoplexia uteri.” This is not the place to discuss these objections—some will suggest themselves. No satisfactory proof has been advanced that arteriosclerosis or atheroma of the pelvic blood-vessels exerts more than an occasional influence in producing uterine hemorrhage.

It will thus be seen that the occurrence of uterine bleeding is not necessarily associated with anatomic findings in the uterus, which is the immediate source of the menstrual flow, or in the other pelvic organs which participate to a greater or less extent in the menstrual phenomenon. Shall we, in spite of our failure to find an anatomic explanation in many cases of uterine bleeding, still tell ourselves that it *must* be there? Or shall we make our study more comprehensive, remembering that other factors than the organs themselves are concerned in menstruation, and that abnormal uterine bleeding may perhaps be due to aberrations of these other cogs in the menstrual mechanism?

What are these other links in the menstrual chain? What, first of all, is the fundamental cause of menstruation? We have for many years looked on the ovary as primarily responsible for the occurrence of menstruation. Certainly the complete removal of all ovarian tissue as a rule—some say always—causes cessation of menstruation. There is abundant proof that this function of the ovary is dependent on an internal secretion which it contributes to the bloodstream. On the other hand, many facts are known which indicate how intimately the ovarian hormone is bound up with that of many other glands in the body which produce internal secretions. There are some indeed, who maintain that, important as the ovary is to menstruation, the ovarian hormone is not the ultimate cause of the latter. According to this theory, which is suggested by so good an observer as Halban, the ovary is merely the activator of the real underlying cause, which resides in some other part of the body, most likely in some of the ductless glands. It is no longer a mere theory that the ductless glands form a functional chain throughout the body, and that disturbances of any one of them are apt to exert a far-

reaching effect on other members of the group. However indispensable the function of the ovary in menstruation, an important contributory rôle must be assigned to these other organs of internal secretion. There is much evidence of a functional relationship between the ovary and the thyroid, the ovary and the hypophysis, and the ovary and the suprarenals. As regards the other ductless glands, the evidence is not quite so imposing, though many scattered facts point to more or less correlation of function in the case of almost all of them. I shall not here discuss the still disputed question as to which element or elements of the ovary produce the hormone which exerts such a profound influence on menstruation.

How does the ovarian hormone bring about the hyperemia of menstruation? Either it acts directly on the blood-vessel walls or else it produces its effect through the vasomotor nerves. There is some reason for supporting the first of these views, although the second manner of action is more commonly found in the body. Physiologists, I believe, are prone to speak of any relay station in the spinal cord or elsewhere as a “center,” and from this point of view some have spoken of a so-called menstrual center, usually described as being located in the lumbar portion of the spinal cord. While there seems to be no definite knowledge concerning such a center, there is no question that the vasomotor nerves of the pelvis play an important rôle—whether essential or only supplementary we cannot say—in the production of the hyperemia which is perhaps the most conspicuous feature of menstruation. The vasomotor nerves are offshoots of the sympathetic nervous system, and through the rami communicantes are linked up with the cerebrospinal system and even with the psychic centers in the brain. The significance of these facts I shall elaborate later in my paper.

From this brief summary it may be seen that the factors concerned in menstruation are (1) an underlying cause; (2) a nervous mechanism, essentially vasomotor in nature, and (3) the uterus, and especially the endometrium. The cardinal theme of my paper is that uterine bleeding may be due to disturbance or perversion of any of these factors, and that an intelligent study of a given case must embrace a search, not for anatomic alterations alone, but for deviations from the normal physiology as well. In accordance with the foregoing views of normal menstruation, I suggest that the causes of uterine bleeding may be divided into three groups: (1) the fundamental causes, embracing disturbances of the internal secretions, either of the ovary or of some of the other *Blutdrüsen*; (2) the nervous causes, which exert their effect mainly through the agency of the vasomotor nerves, and (3) the anatomic causes, which have to do with structural alterations in the pelvic organs, pelvic blood-vessels or, for that matter, in the blood itself.

A discussion of the last group is scarcely within the province of my paper. I can only repeat that the cause of uterine bleeding is most frequently to be found in this group, which embraces such common conditions as uterine and ovarian neoplasms, adnexal inflammations, incomplete miscarriage, etc. My discussion will therefore be limited to the fundamental and nervous causes of uterine hemorrhage, both of which are admittedly less frequently observed than the anatomic group.

3. Theilhaber: Arch. f. Gynäk., 1902, lxxvi, 1.

4. Pankow: Arch. f. Gynäk., 1906, lxxx, No. 2.

5. Slocum: Surg., Gynec. and Obst., April, 1908.

In the consideration of the fundamental causes of uterine bleeding, we at once find ourselves on very uncertain ground. In the enormous literature concerning the internal secretions, there is much less of fact than of fancy. When the ductless gland faddist, if you choose to call him so, blows his warm breath, on the molecule of fact, it is quite apt to be vaporized into the mountain of hypothesis and speculation. And yet from this great nebula of hypothesis new facts are constantly being crystallized.

As already stated, it is with the ovary that we are primarily concerned in the consideration of menstruation and its various disturbances. The study of the ovarian hormone, like that of the other internal secretions, is much easier along negative than along positive lines. To illustrate, by mere extirpation of the ovaries we may show that cessation of menstruation is due to loss of the ovarian hormone. But it is far more difficult to bring about a condition of hyperfunction of the ovaries, nor is it even certain that such a condition of "hyperoophorism," analogous to hyperthyroidism, may be produced. In the case of the thyroid, mere feeding of the gland extract to a normal person suffices to bring about hyperthyroidism. On the other hand, the possibility of producing hyperoophorism by feeding ovarian extract has been questioned. This is perhaps not surprising when we consider how little we know concerning the nature and characteristics of the ovarian hormone or hormones, and how gradual and inconspicuous would probably be the effect of an excess of ovarian secretion, even though we were sure that this could be produced by mere feeding of the extract. A number of cases have been recorded in which hyperoophorism has apparently been brought about by the latter method. A rather striking case in the recent literature is that of Adler.⁶ It was that of a girl of 21, who had menstruated normally since the age of 15, but who after a short course of an ovarian extract for the first time in her life menstruated four days before the expected time, the flow being much more profuse and lasting longer. After the cessation of the treatment menstruation resumed its old periodicity, duration and intensity.

Much more interesting, however, is the effort of Adler to determine the existence of hyperoophorism in an indirect manner. His method requires a word of explanation. As with the other viscera, the principal nerve-supply of the uterus is derived from the sympathetic. A very revolutionary change is now in progress as regards our ideas of the physiology of the sympathetic nervous system, or, as it is frequently called, the vegetative system. According to the classical description of Langley, the entire vegetative system may be divided into two portions. First, there is the gangliated cord which stretches along each side of the midline of the body, and which may be called the sympathetic system proper. Secondly, many of the autonomic functions of the body are in part regulated by certain cerebrospinal nerves derived principally from the brain and from the sacral portion of the spinal cord. These nerves constitute what is therefore called the craniosacral autonomic system. From the fact that the vagus nerve is the most prominent constituent, this system is also spoken of as the vagal. Kraus, again, speaks of it as the parasympathetic. The distinction between the two systems can perhaps

be best illustrated by the case of the heart. This organ receives its accelerator supply from the sympathetic, its inhibitory supply from the vagus. The former is the whip of the heart, the latter the brake. This antagonism in function is characteristic, being noted in all the other organs, including the uterus. To proceed to the practical application of these facts, it has been found that certain drugs show an elective affinity for one or the other of the two systems. Epinephrin, in accordance with the well-known law of Langley,⁷ affects especially the sympathetic, its injection causing precisely the same effect on an organ as does stimulation of its sympathetic nerve-supply. It is therefore spoken of as a sympathicotropic drug. On the other hand, pilocarpin is perhaps the best-known of a group of drugs which exert a special action on the vagal system, and which are therefore spoken of as vagotropic drugs. To carry the point still farther, it has been found that certain endogenous chemical substances of the body, more particularly the various hormones, exhibit a special influence on one or the other of these two systems. There is reason

Diagram showing principal physiologic factors concerned in menstruation. *D*, the ductless gland chain, the ovary being the organ most intimately related to menstruation. *S* and *V*, the two physiologic divisions of the vegetative nerve system—the sympathetic proper and the craniosacral autonomic, respectively. Both are traceable to the cerebrospinal system, and the sympathetic is seen to be directly connected with the ductless gland chain, notably at *x*, with the adrenal.

to believe that before very long all the various hormones of the body will be divisible into two groups, one sympathicotropic, the other vagotropic. Much has already been done along this line.

Studies on the ovarian hormone from this point of view are still very meager. The observations of Adler,⁶ however, are worthy of mention. After removal of the ovaries, and to a less extent in cases of ovarian insufficiency manifesting themselves by amenorrhea and genital hypoplasia, he finds that there is an increased susceptibility to small doses of the sympathicotropic epinephrin. On the contrary, in the study of a series of cases of uterine bleeding, he observed no reaction whatsoever to epinephrin, while on the other hand there was a marked susceptibility to even very small doses of the vagotropic pilocarpin. This result he regards as justifying the view that these cases of uterine bleeding were due to overfunction of the ovary.

This conclusion, however, is open to serious question, when we consider that many structures other than the ovary contribute to the characteristic reac-

6. Adler: Arch. f. Gynäk., 1912, xcv, 349.

7. Langley: Schaefer's Text-Book of Physiology, ii.

tions. Even so, however, such work as this is of exceeding value. For perhaps the first time, we are now able to attack the hitherto rather intangible problem of the internal secretions by simple clinical methods instead of by complicated laboratory investigation. Just what practical results will accrue from this new line of endeavor remains to be seen. In the light — or shall I say the darkness? — of our present knowledge of the influence of various hormones on menstruation, the present methods of organotherapy in gynecologic disorders are largely empiric. Until we can put our figurative finger on the specific hormone or hormones at fault, there is little hope of a rational therapy of the various menstrual disorders which are now so indiscriminately treated by various organic extracts. Even before the realization of such an ideal, however, we may hope for advance through studies based on the demonstrated relation between the vegetative nerves and the internal secretions of the body, including that of the ovary. If we cannot definitely determine that uterine bleeding in a given case is due to disturbance of some specific hormone, would it not be a real advance, for example, to be able to say that it is characteristically associated with a condition of vagotony? Even therapeutic possibilities suggest themselves from work along this line.

Though as yet on a small scale, I have entered on the study of this fascinating subject, and as far as uterine bleeding is concerned, have had results in part at least similar to those of Adler. The most marked vagotonic reactions which I have noted have been in four cases of hemorrhage in girls at puberty. In all these cases, the injection of from 1/15 to 1/10 grain of the vagotonic pilocarpin gave a most pronounced reaction, characterized especially by profuse perspiration, a feeling of warmth, salivation, contraction of the pupils, etc. On the other hand, the strongest epinephrin reactions have been noted in women at the menopause. The injection of 1 mg. of epinephrin (about 15 minims of the 1:1,000 solution) caused pronounced tremor, nervousness, a feeling of cold or chilliness, dilatation of the pupils, rapid heart-beat, and rise of blood-pressure. It must not be supposed, however, that such methods will enable us to work out the problem of uterine bleeding by rule of thumb. Many apparent contradictions have occurred in my own work, some of them difficult or impossible of explanation. For details as to the theory and general method of such study, I would refer those interested to the articles of Adler,⁸ Eppinger and Hess,⁹ and Barker and Sladen.¹⁰ My own results I hope to record in detail in a later paper.

Another physiologic factor in the causation of uterine hemorrhage which is closely associated with the activity of the glands of internal secretion has reference to the presence of some local factor in the endometrium which is capable of diminishing the coagulability of the blood and thus predisposing to bleeding. Sturmdorf¹⁰ has suggested that the endometrium, under the influence of the ovarian hormone, manufactures a substance which inhibits the normal coagulability of the blood. The experimental work of Schickele¹¹ and others has led to somewhat similar conclusions. Schickele's results are based on the

study of the inhibiting influence of extracts and expressed juices of the uterus and ovaries on the coagulability of the blood. When there was abnormal bleeding from the uterus, he found that the inhibitory powers of the ovarian extracts are greater than those of the uterus; but when profuse menstrual bleeding was present, it was found that the extracts from the uterus exerted a much greater inhibiting effect on coagulation. This would seem to indicate that bleeding is associated with the accumulation of coagulation-inhibiting substances in the endometrium. Without going into greater detail, I need only say that the work of Schickele indicates that the inhibiting substances are formed in the ovaries and given off in the uterus. When uterine bleeding is present, there is an excessive amount of these inhibiting substances in the uterus. Schickele suggests that this is probably due to over-activity of the ovary, so that ultimately this local physiologic factor in the causation of the bleeding is apparently traceable to a fundamental disturbance in the mechanism of the menstrual process. The occasional success of the operation of curettage in the relief of uterine hemorrhage, even when the endometrium is anatomically normal, may perhaps be explained on the basis of this work, the good result being due to the removal of the inhibiting substance rather than of the endometrium.

As to the dependence of uterine bleeding on disturbance of other internal secretions than that of the ovary, I can only mention the possibilities, accurate observations still being very meager. That a functional relationship exists between the generative organs and the thyroid gland is now a well-established fact. The swelling of the thyroid at menstruation and during pregnancy, and the occasional occurrence of even acute hyperthyroidism after removal of the ovaries, are manifestations of this physiologic correlation. While observations are not unanimous on this point, it seems to be true that hyperthyroidism frequently includes among its other symptoms menorrhagia or metrorrhagia, while hypothyroidism, on the other hand, is more commonly associated with the occurrence of amenorrhea or scanty menstruation. These conclusions are based on the study of outspoken cases of deficient or excessive thyroid secretion, as the case may be. When one considers the frequency of minor grades of thyroid disturbance, and how often they are overlooked, it is easy to appreciate that a certain proportion of cases of uterine bleeding may be thyroid in origin.

Concerning the possible influence of other ductless glands, we can say even less of a definite nature. That the pituitary exerts an influence on menstruation is illustrated in the well-recognized adiposogenital dystrophy of Frölich, due to pituitary deficiency and characterized clinically, among other symptoms, by amenorrhea or scanty menstruation. This being true, one is tempted to believe that the opposite condition, menorrhagia, is perhaps sometimes due to hyperpituitarism. Of this, however, there is no direct proof, and as a matter of fact, many cases of hyperpituitarism appear to be associated with amenorrhea. Here again we encounter the possibility that there is more than one hormone concerned, or that the bleeding is due to a perversion of the secretion — a dyspituitarism — rather than to a simple excess or deficiency. In the case of the adrenals, the work of Bulloch and Sequeira, and many others leaves no reason to doubt

that these bodies are closely correlated with the generative organs, although there is no evidence as yet that they may be causative factors in uterine bleeding.

We come, finally, to a consideration of the nervous causes of hemorrhage from the uterus. A few years ago it would have been considered only a fanciful hypothesis to attribute to the nervous system a part in the causation of uterine bleeding. When we consider, however, that such a condition as exophthalmic goiter appears often to follow severe nervous shock, and that Crile has demonstrated that the emotion of fright produces definite structural alterations in the brain-cells, we must certainly have greater respect for the nervous system as a disturber, not only of function, but also of structure. There are many functions of the body which are essentially autonomic, but in which a vestige of voluntary control is still evident. In defecation and micturition the control of the will is still an important factor. In the case of such a function as digestion, the voluntary factor is far less important, while in the case of menstruation, to go still farther, the influence of the volitional factor is unrecognizable under normal conditions. And yet even with menstruation the higher centers still retain at least a vestigial degree of control, and under pathologic conditions, this may be greatly exaggerated.

The nervous factor in uterine bleeding has already in a measure been touched on in the discussion of the vegetative nerves as they influence the internal secretion of the ovary. It is scarcely necessary to add that what is true of their influence on the ovarian secretion is equally true as regards their influence on the other internal secretory tissues. No one can as yet say to what extent the influence of these various internal secretions on menstruation is directly chemical, and to what extent it is exerted through the medium of the vasomotor nerves. Like the vasomotor nerves in all other parts of the body, those supplying the generative organs arise ultimately from the cerebrospinal axis, the primary vasomotor center being definitely located in the floor of the fourth ventricle. The center is linked up with the psychic center, thus explaining the occasional occurrence of uterine bleeding as a result of severe emotional disturbance of one form or another. A number of such cases have come under my own observation, of which the following two are typical:

A woman of 42, a multipara, had always menstruated regularly, the flow lasting usually about four days. A menstrual period commenced, Dec. 23, 1913. December 26, as the flow was abating, a Christmas tree in her home took fire, setting the room ablaze. The woman received a severe fright, and within a short while, a profuse hemorrhage set in, lasting for six or eight hours, and then gradually abating.

A girl of 15, who had commenced to menstruate at 13, was brought to the dispensary with profuse uterine bleeding. Her menstruation had never been regular, amenorrhea being frequently noted. There had never previously been any excessive flow. The history given was that an assault on the child had been attempted on the preceding day. On account of the bleeding, it was thought that there might have been some local injury. Examination disproved this, the assault having evidently been unsuccessful. Regular menstruation, lasting three days, had occurred five weeks previously. The hemorrhage in this case was apparently due to the nervous shock associated with the attempted assault.

A number of other cases of this type might be cited. Similar cases are reported by Ehrenfest¹² and others.

That hemorrhage may be of neurotic origin has been abundantly shown by Brown-Séquard, von Recklinghausen and others. There is nothing very revolutionary in such an explanation, for many other phenomena might be mentioned which illustrate the influence of the psyche on processes which in themselves are essentially autonomic—the “watering” of the mouth at the sight or smell of food, the acceleration of the heart from fright or joy, the sweating so characteristic of intense anxiety, etc. Even more apropos, since they illustrate the influence of psychic disturbances on the vasomotor apparatus, are such phenomena as the blush of shame or embarrassment, or the bleeding from the stomach or even from the skin which has been observed in highly nervous or hysteric women. From a theoretic point of view as well as from clinical experience, we may therefore conclude that certain cases of uterine bleeding are undoubtedly neurotic in origin, or, more properly, perhaps, “angioneurotic.”

The close interlocking of the nervous system and the ductless glands makes it possible that severe psychic disturbances produce menstrual aberrations by a direct effect on the functions of the internal secretory glands. Such a phenomenon would be analogous to the glycosuria which has been shown to occur at times in conditions of severe fright and other emotional disturbance, and which is explained as being due to a nervous excitation of the adrenal bodies. This has been corroborated by the failure of the glycosuria to appear if the nerves supplying the adrenals have previously been cut, thus severing the connection of the latter with the psychic centers. I mention this to emphasize the fact that a direct connection between the psychic centers and the ductless gland chain has been demonstrated experimentally. The nervous factor in uterine hemorrhage, like that of the internal secretions, is most apt to make itself manifest at those periods when the woman's menstrual equilibrium is already unstable, that is, puberty and menopause.

SUMMARY

1. The proper basis for the study of uterine bleeding is the study of normal menstruation, along physiologic as well as anatomic lines.

2. The factors concerned in normal menstruation are (a) an ultimate cause, residing in the ductless gland chain; (b) a nervous mechanism, essentially vasomotor in character; (c) the pelvic organs, and especially the uterus.

3. The causes of uterine bleeding may therefore be grouped as (a) fundamental, involving disturbances of the internal secretions; (b) nervous, exerting their effect mainly through the vasomotor nerves; (c) anatomic, in which structural changes are present in the uterus or other pelvic organs.

4. Most frequently the exciting cause of uterine hemorrhage is anatomic, the lesion being in the uterus, tubes, ovaries, blood-vessels or even the blood itself.

5. In a not inconsiderable number of instances, bleeding is due to fundamental or nervous causes, especially at the two extremes of menstrual life, puberty and the menopause.

6. There is good reason to believe that much light will be thrown on the rôle of the fundamental causes, and perhaps even of the nervous causes, by clinical methods of study which are based on the relation known to exist between the ductless gland apparatus and the vegetative nerve system.

RADIUM IN THE TREATMENT OF UTERINE
HEMORRHAGE AND FIBROID TUMORS *

HOWARD A. KELLY, M.D.

AND

CURTIS F. BURNAM, M.D.

BALTIMORE

The association of several diverse pathologic conditions may occasion surprise. Our excuse for presenting them together in this instance is that they have certain characteristics in common, namely, they are all benign, all chiefly troublesome on account of hemorrhage, and all remarkably united in their ready response to ray-therapy.

Until recently the control of uterine hemorrhage and the relief of symptoms of pressure occasioned by fibroid tumors have been possible with certainty only by radical surgical procedures.

The benign conditions which we wish to consider in this paper fall readily into four groups, excluding uterine hemorrhages due to cancer and other malignant disease, as well as those due to inflammatory disease of the adnexa, and those due to pregnancy and miscarriage.

The first group includes cases in adult women in which there is marked menorrhagia or metrorrhagia with no disease of the pelvic organs, except perhaps a slight enlargement of the body of the uterus. The endometrium taken from such uteri is microscopically normal. These cases belong to the so-called myopathia hemorrhagica class.

The second group takes in most of the hemorrhages which occur in young girls. In many of these the local findings are exactly as in Group 1. In some instances the condition is similar to that found in Group 3 (polypoid endometrium). Although pathologically this group cannot be separated from the others, it presents marked and distinctive features clinically, and in especial it differs radically in the indications for treatment. It is most important with these patients to avoid both sterility and mutilation.

The third group includes patients suffering with uterine hemorrhages who show no pathologic condition except an extensive polypoid overgrowth of the endometrium, which is generally termed polypoid endometritis.

The fourth group includes true uterine myomas, whether they are causing hemorrhage or merely giving discomfort through pressure on adjacent organs. Here the true aim of treatment is not only to regulate or stop the bleeding, but also to bring about the complete disappearance of the tumor.

MODE OF ACTION OF ROENTGEN AND RADIUM RAYS
ON UTERINE HEMORRHAGIC CONDITIONS,
ESPECIALLY FIBROID TUMORS

It has been firmly established both from animal experimentation and clinical observations on human beings that the Roentgen ray and the penetrating rays from radium are capable of destroying the primordial follicles of the ovary and the spermatogenic cells of the testicle. We have but to mention the names of Albers-Schoenberg, Brown, Osgood, Halberstaetter, Fraenkel, Faber, and many others who have contrib-

uted to our accurate knowledge in this direction. As it is the primordial follicles which give rise to the corpora lutea and determine menstruation, these results suggested at once that the penetrating rays might offer a means of causing amenorrhea and sterility. From the older literature it was known that many fibroids ceased to bleed and grew smaller after a double oophorectomy. A case of complete disappearance of a large fibroid tumor after this operation occurred in the service of one of us (H. A. Kelly) at the Johns Hopkins Hospital and is reported.¹⁰ Reasoning on the basis of similar experiences, it was felt that the ray therapy had its primary effect on the ovaries and secondarily controlled the pathologic conditions in the uterus. Most of the technics devised for radiation based on this idea have particularly endeavored to concentrate a maximum amount of rays on the ovaries, leaving the tumor more or less out of consideration.

It has been well established both from Roentgen-ray and radium radiation that an obliterative endo-arteritis occurs almost invariably in the field radiated. We have noticed this condition in a marked degree in a number of cases in which we have operated after extensive radiation with radium. The natural conclusion therefore is that the effect on a fibroid tumor is due to the anemia following the occlusion of its nutritive vessels.

Against the conception that the influence on fibroids is mainly indirectly through the ovaries are the facts that many fibroids grow after the menopause, that some grow after the removal of the ovaries, and that marked regressions occur in tumors treated by the ray method in patients past the menopause. For these reasons we believe that there is a *specific and direct action of the rays on the tumor itself*, and we further believe that this happy result can be secured *quite independently of any action on the ovaries*. In the series of fibroids to be recorded in two cases the tumor disappeared without cessation of menstruation! In another already past the menopause there has been marked regression from a single treatment!

TECHNIC

In the tables we give with each case the amount of radium and the duration of the application. The reader will observe at once a wide variation in the individual cases. While we feel that the results given can all be duplicated by the same technics, we do not consider the matter of dosages in any sense settled. Our plan has been steadily to increase the milligrammage while decreasing the time. This is not only for economy and comfort to the patient but because of the better results and fewer complications occurring. The ideal method, where it is not desired to secure amenorrhea, is to limit the radiation so far as possible to the tumor itself, avoiding touching the ovaries. This is best secured by intra-uterine applications. It is sometimes well to reinforce such treatments by abdominal radiation either with radium or the Roentgen ray.

The technic advised is filtration through glass 0.5 mm. of platinum, 0.5 mm. of zinc foil, and 0.3 mm. of rubber. Such an apparatus, suitable shaped, is carefully introduced directly into the uterine cavity. Cervical applications alone we find to be less reliable, demanding much more radiation to secure results. As a preliminary to the introduction of the radium, the patient is given nitrous oxide and then thoroughly curetted, and examined carefully under complete anes-

TABLE 1.—FIRST GROUP BLEEDING UTERI "MYOPATHICA HEMORRHAGICA"

No.	Name	Age	Date	Duration	Severity	Previous Treatment	Pelvic Examination	Treatment	Immediate Results	Complications	Final Results
289	Case 1 Miss L. H.	44	9/ 3/13	6 months	Marked bleeding; anemic	Medicinal. No benefit.	Normal organs	100 mg. 24 hrs.	Nauseated 3 days; no fever; abdom. tenderness 2 weeks.	None	Slight menstrual period October 3. None since. General health splendid. Slight menopaual symptoms.
291	Case 2 Mrs. R. S.	38	9/11/13	2 years	Rather severe; marked anemic.	Medicinal only. No benefit.	Normal organs	80 mg. 24 hrs.	24 hrs. nausea; abdom. discomfort 3 weeks. some discharge; leukorrhea.	None	Slight period October, 1913. None since. Splendid health. No menopaual symptoms.
335	Case 3 Miss S. McL.	27	10/22/13	2 years	Very severe; anemic.	Local applications iodine, repeated curettings without result.	Normal organs	100 mg. 9 hrs. 10/23; 60 mg. Ra. 18 hrs., 12/1/13.	Menstruation November and December; slight nausea for 24 hrs.	None since	Complete amenorrhea. No menopaual symptoms; general health splendid.
383	Case 4 Mrs. F. M.	42	11/14/13	1 year	Very severe; anemic.	Medicinal. No benefit.	Slight enlargement of uterus.	60 mg. 10½ hrs.	None	None	Slight bleeding in December. None since. Slight menopaual symptoms.
385	Case 5 Mrs. J. D.	41	11/18/13	4 years	Very severe; marked anemic.	Local applications; general medication; curettement.	Uterus size of 6 weeks' pregnancy.	70 mg. 12 hrs.	Nauseated 1 day; headaches; some abdominal pain 2 weeks.	None	Menstrual period in December. None since. General condition excellent. Uterus reduced to normal size. Marked menopaual symptoms.
348	Case 6 Mrs. J. H. H.	45	12/18/13	1 year	Excessive; anemic.	Medicinal. No benefit.	Normal organs	100 mg. 6 hrs.	No discomforts	None	In January normal period. Since then no bleeding. No menopaual symptoms. Splendid health.
272	Case 7 Mrs. A. B.	28	7/21/13	Several years	Marked upset; marked anemic; general weakness.	Curettements, local applications, general medication; no benefit.	Normal organs	60 mg. 24 hrs.	Nauseated 2 or 3 days; uterine discharge 2 weeks; slight abdominal discomforts 2 weeks.	None	No further menstrual periods. Slight menopaual symptoms. Splendid general health.
786	Case 8 Mrs. C. R. C.	39	4/18/14	4 months	Severe; anemic.	Curettement; medicinal; no benefit.	Normal organs	268 mg. 2 hrs.	None	None	No further menstrual periods to date. Apparently cured. No menopaual symptoms.

TABLE 2.—SECOND GROUP: BLEEDING UTERI IN YOUNG GIRLS

No.	Name	Age	Date	Duration	Severity	Previous Treatment	Pelvic Examination	Treatment	Immediate Results	Complications	Final Results
176	Case 1 Miss F. P.	13	7/ 5/13	1 year with onset of periods.	Irregular, prolonged, severe.	Medicinal	Normal organs; normal endometrium.	20 mg. 5 hrs.	None	None	Normal periods since treatment.
377	Case 2 Miss E. W.	23	11/13/13	Difficulty since onset of periods; very bad 2 yrs.	Moderate; anemic.	Repeated curettings; medicinal; resection of ovaries.	Normal organs; normal endometrium.	12 mg. 7¼ hrs.	None	None	Normal regular periods since treatment.
361	Case 3 Miss E. N.	16	11/ 4/13	2 yrs. since onset.	Quite severe.	Curettings; general medicinal.	Normal organs; normal endometrium.	60 mg. 12 hrs.	None	None	Normal regular periods up to present time.
186	Case 4 Miss A. R.	19	6/ 4/13	1 year	Continuous; not particularly severe; anemic.	Curettement; medicinal.	Normal organs; excessive endometrium; polypoid.	55 mg. 24 hrs.	No menstrual periods for 2 months; some abdominal tenderness.	None	Normal menstruation has returned; patient in splendid condition.
30	Case 5 Miss H. B.	20	2/ 7/13	Several years' irregular bleeding.	Very severe; complicated by organic heart disease.	Curettement; medicinal.	Normal organs; normal endometrium.	400 mg. 7 hrs.; abdominal application.	Nausea; slight rise in temperature.	None	Complete cessation of menstruation; artificial menopause. Some menopaual symptoms.

thesia; this is indispensable to good work. The amounts used intra-uterine in the fibroid cases have varied from 30 mg. to 560 mg. and the time of application from one and one-half hours to forty-eight. In the young girl class the amount of radium introduced has been as small as 12 mg. In speaking of milligrams radium element is meant; whatever the salt and whatever its purity, in all reports the amount in equivalent of radium element pure should be given. In the case of mesothorium, which varies with age, the strength equivalent to radium element at the time of radiation should also always be stated.

In conjunction with Dr. Robert M. Lewis and other workers of the Howard A. Kelly Hospital we have been using radium in the treatment of these bleeding cases for a year and a half and have had in all 39 cases: 8 hemorrhagic metropathies, 5 polypoid endometria, 5 irregular bleedings in young girls, and 21 cases of uterine fibroid tumors. All of these latter have belonged to the class of large or medium tumors, none to the group of small tumors to which the treatment is limited by Chéron.

In the first group, that of bleeding uteri of adult women without any demonstrable pathologic lesion, the eight cases are summarized in Table 1. The average age is 38 years, the youngest 27, the oldest 44. All were suffering from anemia and had not yielded to the palliative measures previously applied. The amounts of radium used varied from 60 to 268 mg., the time of exposure from two to twenty-four hours. In two cases (7 and 8) the bleeding never recurred after the first treatment. In one case (3) a second treatment was necessary. In the remaining 5 cases a normal menstrual period followed at the regular time to be followed by complete amenorrhea. The average time from treatment to complete amenorrhea was 3½ weeks. Mild menopausal symptoms occurred in 3 cases, marked menopausal symptoms in one case, and none in 4 cases. The patients all left the hospital within forty-eight hours and except for a slight abdominal burning which lasted two or three weeks and which was accompanied by some leukorrhea, have had no bad results. All now report themselves in good health.

In the third group, of adult women with uterine hemorrhage and no disease except a polypoid endometrium, there are 5 cases the details of which are given in Table 3. The average age was 43 years; the oldest 49 years, the youngest 35 years. Except in Case 1, in which a combined uterine abdominal and vaginal application was used, only the intra-uterine method was used. The amount of radium employed varied from 100 to 30 mg. The duration of the treatment was from twenty-two to seven hours. With the exception of Case 1, in which bleeding led to hysterectomy five days after application, all were relieved at once by the single application. All these patients were anemic, all had resisted other forms of treatment, all have regained their normal condition since treatment. In 2 cases menopausal symptoms were slight. In 2 cases they were not present. Case 1 is not included as here oophorectomy and hysterectomy was carried out.

In the second group, which includes young girls who were bleeding, there are 5 cases, the tabulation of which is given in Table 2. The ages varied from 13 to 23, the average being 18 years. In addition to the usual medicinal treatments, all but one had had curettages and one had had a resection of the ovaries, with

TABLE 3.—THIRD GROUP: BLEEDING UTERI FROM POLYPOID ENDOMETRIUM

No.	Name	Age	Date	Duration	Severity	Previous Treatment	Pelvic Examination	Treatment	Immediate Results	Complications	Final Results
129	Case 1 Mrs. R. L.	49	2/16/13	3 years	Intermittent; very severe; marked anemia.	Medicinal; local applications; curettage.	Normal organs; excessive endometrium; polypoid.	50 mg. in uterine cavity; 100 mg. in vagina; 100 mg. on abdomen 22 hrs.	Marked nausea and vomiting for 24 hrs.	Continued hemorrhage; hysterectomy 5th day; abdominal tenderness 3 weeks.	Well-marked menopausal symptoms.
88	Case 2 Miss N. H.	35	5/24/13	1 year	Quite severe; marked anemia.	None	Normal organs; excessive endometrium; polypoid.	30 mg. 18 hrs.	Nausea a day or two; uterine discharge 1 month.	None Abdominal tenderness 2 weeks.	No menstruation since treatment; no menopausal symptoms.
245	Case 3 Miss J. W.	47	6/24/13	9 months	Rather severe; marked anemia.	Medicinal only	Normal organs; polypoid endometrium.	70 mg. 16 hrs.	Slight nausea	None Abdominal tenderness several weeks.	No further bleeding; menopausal symptoms mild in 2 months from treatment.
271	Case 4 Mrs. A. H.	40	7/14/13	2 months	Continuous; severe; marked anemia.	None	Normal organs; polypoid endometrium.	50 mg. 24 hrs.	Nausea and vomiting 1 day.	No further menstrual periods; slight menopausal symptoms; abdominal tenderness 1 month.	No further menstruation; slight menopausal symptoms.
758	Case 5 Mrs. A. B.	43	3/4/14	4 or 5 years	Very severe; marked anemia.	Medicinal; frequent curettages; reduction of uterus by operation.	Small normal uterus; other organs normal; polypoid endometrium.	100 mg. 7 hrs.	Nausea; slight headache	None	Entirely well; no menopausal symptoms.

the idea of diminishing the period. All were in general good condition except for the anemia, with the exception of Case 5, in which there was extreme organic heart disease. The amount of radium used varied from 12 to 60 mg. The time of application ran from five to twenty-four hours. In the first three cases the menstrual periods have returned to the normal type and the patients recovered a normal hemoglobin content.

In Case 4 there was amenorrhea lasting two months, then a return of menstruation, which has been a little irregular at intervals of from three to five weeks but never excessive. In the fifth case, where the application was through the abdominal wall, complete amenorrhea with distinct menopausal symptoms was produced. Where we desire to diminish hemorrhage the treatments are short and the milligrammage small, although it is harder to produce a complete amenorrhea in this group than in women over 40.

In the fourth group, which includes the fibroids, there are 21 cases; the average age is 44; the oldest 59 years; the youngest 32 years; menorrhagia, metrorrhagia or both, were present in 19 cases; in one there was normal menstruation, in one no menstruation, as patient was six years past menopause.

The tumors with one exception (Case 10, Table 4) were either large or middle sized. By large we mean those reaching half way to the umbilicus or larger, while middle-sized tumors include those from the size of a two and a half months' pregnancy half way up to the umbilicus.

In 3 cases the tumor was definitely submucous. With the exceptions of Case 5, in which there was an ovarian cyst, and Case 16, a cystic ovary, and Case 20, chronic pelvic inflammatory disease, and Case 8, marked exophthalmic goiter, and Case 10, infection of the tumor and uterine cavity, the fibroid condition was uncomplicated. The amounts of radium and the duration of the application are shown in Table 4.

In Case 8 the application was atypical, in that radiation had been given with the Roentgen ray both prior to and after the radium radiation. Owing to the extreme illness of this patient the ordinary technic was not followed and the application was made through the abdomen. In Case 21, the only failure in the group, the application was also atypical, from the abdomen and from the cervix. At the time this patient was treated it was not realized that the intracervical treatments require much longer times of exposure. Here, owing to the tortuosity of the cervical canal, the introduction of the tubes into the uterus was difficult. After the failure, however, it was thought better not to radiate further, but to treat surgically.

These patients almost invariably suffer from nausea for twenty-four hours, and from abdominal tenderness for from ten days to three weeks, and some of them have leukorrheal discharge for a few weeks. The symptoms above enumerated have been much less marked when large amounts of radium are used for relatively short times. In only one case, No. 20, has any serious complication followed the treatment. Here an inflammatory process was lighted up and a pelvic abscess formed. It healed, however, without operation, and the patient is perfectly well to-day.

EFFECTS ON HEMORRHAGE

In 16 of the 21 cases, complete amenorrhea has been obtained; immediately after the treatment in 6 cases, at the end of one month in 4 cases, at the end of two

months in 4 cases, at the end of several months in one case (3) in which the milligrammage and hours were small. In one case the patient is six years beyond the menopause and there was no bleeding. In one case, No. 21, the treatment failed. In one case, the time since treatment is too short to state the effect. In two cases, and these in our opinion are most important, *the menstrual periods have persisted regularly and the tumors have disappeared*. The details of these two are shown in Table 4, Nos. 4 and 11.

This happy result must be due to the fact that the fibroid has received much more intense radiation than the ovaries, and serves to point the way in which to extend our efforts in this field, that is, *to secure a maximum effect on the tumor with a minimum treatment of the ovaries*. This observation, which reverses the European technic, is possibly applicable to Roentgen ray as well as radium treatments.

The effects on the tumor are as follows:

Case 1, from the size of three months' pregnancy to six weeks' pregnancy.

Case 2, tumor 4 inches in diameter has completely disappeared.

Case 3, tumor 6 inches in diameter has completely disappeared.

Case 4, uterus and tumor size of three month's pregnancy reduced to size of normal uterus.

Case 5, tumor 9 inches in diameter reduced to one 4½ inches in diameter.

Case 6, a huge tumor filling pelvis and lower abdomen has entirely disappeared.

Case 7, uterus and tumor size of a two months' pregnancy reduced to the size of a normal uterus.

Case 8, no report on size of tumor, except that it is markedly smaller.

Case 9, huge tumor filling pelvis and abdomen to umbilicus reduced to the size of a two and one-half months' pregnancy.

Case 10, uterus and tumor the size of three months' pregnancy now a normal uterus.

Case 11, tumor reaching to within 1 cm. of umbilicus reduced to the size of a six weeks' pregnancy.

Case 12, tumor 5 inches in diameter reduced to 2½ inches in diameter. Duration of observation only six weeks.

Case 13, no report obtained.

Case 14, tumor 6 inches in diameter reduced to 1 inch in diameter.

Case 15, tumor size of four months' pregnancy reduced to that of a six weeks' pregnancy.

Case 16, tumor size of four months' pregnancy reduced to one of six weeks' pregnancy.

Case 17, uterus size of three months' pregnancy reduced to a normal uterus.

Case 18, huge tumor filling pelvis and lower abdomen to umbilicus reduced to one-third original size.

Case 19, six years past the menopause, tumor 6 inches in diameter reduced to one 3 inches in diameter, and still decreasing.

Case 20, uterus twice normal size, reduced to normal size.

Case 21, practically no change in size of tumor which is about 4 cm. in diameter.

With intense radiation of the fibroids, the reduction is usually rapid, occurring within two or three months. Where the principal effect has been on the ovary, the disappearance may be much slower extending over months or even years, as in the cases reported by Robert Abbé.⁶

TABLE 4.—FOURTH GROUP: MYOMATA UTERI

No.	Name	Age, yrs.	Date	Duration	Hemorrhage	Size and Position of Tumor	Condition of Other Pelvic Organs	Treatment	Immediate Results	Complications	Final Results
0	Case 1 Mrs. E. R. W.	45	3/18/13	6 months	Menorrhagia, 10 days; clots profuse; some anemia.	Subperitoneal and interstitial uterus and fibroid size of 3 months' pregnancy.	Normal	30 mg. for 48 hrs.	Nauseated 24 hours. No fever. Abdominal discomfort several weeks.	None	Leukorrheal discharge for 2 months. Moderate period in April and May, none since. Uterus size of 6 weeks' pregnancy. General health splendid. Marked menopausal symptoms.
	Case 2 Miss E. G. E.	35	3/23/13	1 year	Menorrhagia, excessive, 10 days; moderate anemia.	Interstitial; 4 inches in diameter	Normal	30 mg. 48 hrs. 3/25/13 38 mg. 48 hrs. 5/1/13 55 mg. 24 hrs. 1/1/14	Nauseated headaches and leukorrhea.	None	Good deal of pain and aching in the back and abdomen. Between May and November regular 3-day periods, scant. Excessive in December. Uterus slightly smaller. No period after January. Uterus normal. Feels splendidly.
175	Case 3 Mrs. F. P.	44	5/17/13	1 year	Rather marked; 7 or 8 days; menorrhagia.	Interstitial; indistinguishable from uterus; 6 inches in diameter; one-half inch between symphysis and umbilicus.	Normal	80 mg. 24 hrs.	Some nausea and vomiting for 24 hours.	None	Moderate flow in June, 1 day in July. No further bleeding. Mild menopausal symptoms. Uterus normal in size. Most of the decrease before December, 1913.
119	Case 4 Miss K.	46	5/27/13	4 months	Menorrhagia, 10 days.	Just reaching out of the pelvis; interstitial; little larger than a 3 months' pregnancy.	Normal	50 mg. 24 hrs.	No discomfort.	None	Missed June period; moderate menstruation in July. No menstruation between July and November. In November fibroid plainly felt in anterior wall 4 cm. in diameter. From December on regular menstrual periods of 3 days' duration. Fibroid entirely gone.
274	Case 5 Mrs. A. A. W.	51	7/22/13	3 years	Menorrhagia; marked anemia apparent.	Interstitial, subperitoneal, submucous; 9 ins.; diameter far up in abdomen.	Ovarian cyst of right ovary 18 in. in diameter.	60 mg. 47 hrs.	Nauseated for 48 hours. Abdominal distress for several weeks mild.	None	No further hemorrhage whatever. By October 25 fibroid reduced to one-half original size. Entirely intrapelvic. Ovarian cyst no more than 1½ inch in diameter. Same condition in June, 1914.
281	Case 6 Miss M. B.	33	8/25/13	2 years	Marked menorrhagia.	Interstitial and subperitoneal; fills entire pelvis and extends 4 fingers above umbilicus.	Normal	120 mg. 18 hrs.	Nauseated, vomiting, some temperature for some days.	For nearly 2 mos. marked discharge; some afternoon temperature	Irregular bleeding for 2 months. Then complete cessation. Very mild menopausal symptoms. Splendid general health. Tumor entirely disappeared.
324	Case 7 Miss E. B.	43	10/ 4/13	2 or 3 years	Menorrhagia low days; very low hemoglobin; menorrhagia for 1 month before treatment.	Interstitial and subperitoneal; uterus size of 2 months' pregnancy; one subperitoneal nodule 1 inch in diameter.	Normal	80 mg. 24 hrs.	Nauseated for 24 hours. Some leukorrhea and abdominal tenderness for 4 weeks.	None	One moderate period in December. Complete amenorrhea. Uterus normal in size. Slight menopausal symptoms. General health splendid.
332	Case 8 Mrs. M. M.	40	10/ 7/13	4 years	Menorrhagia and metrorrhagia; 40 per cent. condition of exophthalmic goiter complicates situation.	Subperitoneal, interstitial, submucous; immense tumor filling entire pelvis and lower abdomen to level of umbilicus.	Not made out.	Abdo. 734 mg. 6 hrs. 484 mg. 4 hrs.	Thyroidism, nausea and vomiting, for a week. Rather high fever.	Thyroidism	Patient had Roentgen-ray treatment by Dr. Stern of New York. Although tumor decreased bleeding continued in November and December. Further Roentgen-ray treatments were given by Dr. Stern. Amenorrhea reached in January. Since then no bleeding. General health has been excellent. Tumor reported to be much smaller.

TABLE 4.—FOURTH GROUP: MYOMATA UTERI—(Continued)

Case	Age	Date	Duration	Menstruation	Uterus	Not made out	100 mg. 12 hrs.	Marked nausea; fever for	None	Since the treatment in January no hemorrhages. On several occasions slight bleeding. Uterus now size of 2½ months' pregnancy, freely movable. Hemoglobin and general condition excellent.
475	Miss A. D. S.	48	1/4/14	4 years	Marked menorrhagia; marked anemia; 30 per cent. hemoglobin; foul discharge; daily fever.	Not made out	100 mg. 12 hrs. April 25 on abdomen 1 hr. 40 min.	Marked nausea; fever for 10 days; purulent discharge from uterus.	None	Since the treatment in January no hemorrhages. On several occasions slight bleeding. Uterus now size of 2½ months' pregnancy, freely movable. Hemoglobin and general condition excellent.
637	Case 10 Miss O. F. E.	40	2/22/14	7 years	Menorrhagia and metrorrhagia; marked anemia and general symptoms from anemia; shortness of breath; hemoglobin 50 per cent.	Normal	100 mg. 10 hrs.	Nausea and considerable upset for 2 days; abdominal tenderness and miserable feeling for 6 weeks which kept her in bed.	None	No menstrual period after a moderate one in March. Reports she is feeling splendidly, better than for years. The growth has entirely disappeared.
681	Case 11 Miss B. S.	39	3/16/14	About 1 year	Menorrhagia and metrorrhagia; marked anemia.	Normal	300 mg. 1½ hrs. April 25 1,100 mg. 2½ hrs. on abdomen.	Twenty-four hours nausea; soreness in abdomen for 10 days; temperature 1 degree above normal for 8 hrs.	None	Normal menstrual periods in March, April, May and June. On April 25 growth one-half original size. On June 14 growth found to be entirely gone.
825	Case 12 Mrs. A. L.	38	4/30/14	1 year	Menorrhagia marked.	Normal	560 mg. 3 hrs.	Little nausea	None	Rather profuse menstrual period in May. None up to present time in June; growth is about half original size.
771	Case 13 Mrs. L. H. C.	44	4/20/14	1 year	Menorrhagia 10 days, but not very anemic looking.	Normal	400 mg. 1½ hrs.	None	None	No report secured.
533	Case 14 Mrs. C. N. B.	43	10/8/13	4 years	Menorrhagia	Normal	60 mg. 24 hrs. 300 mg. 21 hrs. from abdomen.	Nausea 3 or 4 days, marked discomfort in pelvis for 1 month.	None	No further menstrual period; general health splendid; uterus normal in size, small, attached to its right wall; a small pedunculated myoma 1 in. in diameter.
334	Case 15 Mrs. C. E. D.	40	10/20/13	2 years	None	Normal	100 mg. 26 hrs. 60 mg. on abdomen 1½ hrs.	Nausea for 24 hours.	None	Normal menstrual period in November; none since then; general condition splendid; no menopausal symptoms; tumor practically gone; uterus freely movable; slightly larger than normal; no fibroid can be felt.
370	Case 16 Mrs. H. W. T.	59	11/6/13	4 years	Although 59 yrs. old patient is apparently still menstruating; for 4 years has been having irregular excessive menstrual periods.	Apparently cystic left ovary.	100 mg. 24 hrs.	No upset.	None	No further bleeding; splendid health; growth reduced to one-third original size.
394	Case 17 Mrs. A. McG.	16	11/18/13	2 years	Rather marked menorrhagia; symptoms of pressure.	Normal	60 mg. 17½ hrs. 60 mg. 2 hrs. 1/6/14.	Period in December, rather excessive; none since.	None	Feels splendidly; no menopausal symptoms; no bleeding; tumor entirely gone.
375	Case 18 Mrs. W. T. D.	33	12/10/13	1½ years	Menorrhagia 8 days.	Not made out	60 mg. 18½ hrs.	No disturbance.	None	One menstrual period; since then complete amenorrhea; growth reduced to one-third original size; splendid health.

TABLE 4.—FOURTH GROUP: MYOMATA UTERI—(Continued)

No.	Name	Age	Date	Duration	Hemorrhage	Size and Position of Tumor	Condition of Other Pelvic Organs	Treatment	Immediate Results	Complications	Final Results
792	Case 19 Miss M. L. C.	49	4/25/14	At least 10 years.	None. Patient is past menopause 6 years.	15 cm. in diameter, in right broad ligament; uterus to left of tumor; size of 6 weeks' pregnancy.	Normal	150 mg. 6 hours	None except leukorrhoeal discharge.	None	June 5 tumor only 7 cm. in diameter; general condition of patient excellent.
614	Case 20 Mrs. A. H. M.	46	2/6/14	1 year	Very marked menorrhagia; marked anemia.	Uterus about twice normal size; one sub-peritoneal fibroid on anterior wall measures 4 cm. in diameter.	Pelvic inflammatory disease; chronic	170 mg. 13 hrs. 15 min.	Nausea and vomiting; some temperature; abdominal pain for 3 weeks.	Lighting up of pelvic inflammatory disease with formation of pelvic abscess.	No further menstrual periods; pelvic abscess healed spontaneously; no menopausal symptoms; uterus normal in size; general condition splendid.
340	Case 21 Miss A. A.	32	10/8/13	2 years	Menorrhagia 8 days.	Uterus 10 cm. in diameter, round and globular.	Normal	30 mg. 25 hrs. 10/19/13 300 mg. 11 hrs. abdominal, 10/19/13 35 mg. 10 hrs. 11/18/13 35 mg. 12 hrs. 11/20/13 60 mg. 25 hrs. 1/7/14 400 mg. 6 hrs. abdominal 1/7/14	No upset except nauseated a few hours after application.	None	Neither tumor nor hemorrhages markedly changed. The applications here were to the cervix and not intra-uterine. Radical operation carried out 3/14/14.

CONCLUSION

We feel sure as the result of these remarkable experiences that radium offers a marvelous means for controlling, as well as for completely doing away with uterine hemorrhages, in the classes of cases cited.

We believe also that it is perfectly suited to secure the disappearance of fibroid tumors. A radium treatment ranks in severity as scarcely more serious than a simple uterine curettage.

In its brilliancy of curative results it is fully equal to radical surgical procedures while offering the advantages of freedom from danger, pain, suffering and the various postoperative complications and sequelae. Furthermore, when radium fails we still have the operation to fall back on and have not lost in the waiting. As compared with the Roentgen ray, radium is simpler of application, more rapid in bringing about the desired effect, and finally is better in that it acts on the diseased organ, the uterus, with more intensity than on the ovaries. Radium offers the possibility in the fibroid cases of doing away with the tumor without destruction of the ovaries.

We also insist that the fibroid itself should receive the major radiation, whether with the Roentgen ray or with the radium.

The radium can bring about a complete amenorrhea at any age.

The menopausal symptoms which follow this amenorrhea are absent in 50 per cent. of the cases and mild in nearly all of them.

We insist on the intra-uterine application, in contradistinction to the vaginal or cervical, and in this connection wish to contrast the shortness of the radiations in hours as compared with the exposures reported by Chéron⁸ and Gauss and Krinski.⁹ We feel that it is quite possible that suitable abdominal radiation with radium or the Roentgen ray may add to the rapidity of the results.

1418 Eutaw Place.

ROENTGENOTHERAPY IN UTERINE HEMORRHAGE*

GEORGE E. PFAHLER, M.D.

PHILADELPHIA

The treatment of uterine hemorrhage by means of the Roentgen rays, is no longer a novelty, but has become an established method in most of the leading clinics in Europe, and is being well established in America. The first cases were treated and placed on record ten years ago by Deutsch. Since then reports have been made by several hundred roentgenologists and gynecologists, and the number of cases now definitely recorded are considerably over a thousand. There has been sufficient time for all the doubts and fears to have materialized, but instead, all hopes have been realized, the technic has been fairly well established, and the indications and contra-indications reasonably well outlined, so that to-day the method stands as one of the most brilliant achievements of roentgenology.

In 1904 Deutsch¹ found that the rays relieved four cases of uterine hemorrhage connected with fibroids. This report seemed to have been forgotten until

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.
1. Deutsch: Die Radiotherapie bei Gebärmuttergeschwülsten, München. med. Wchnschr., 1904, p. 1646.

Foveau de Courmelle² made a report on forty-five cases of uterine fibroids in 1906, and on fifty-three in 1907. I³ began treating these cases in January, 1906. Since then the publications on this subject have been so numerous that it would require all the time allotted to me for this paper, if I only referred to them.

THEORY OF THE ACTION OF THE ROENTGEN RAYS IN GYNECOLOGY

It has been proved by experiments on animals and human beings (Albers-Schonberg,⁴ Phillips,⁵ Halberstaedter,⁶ Heineke,⁷ and others), that the ovaries and testicles are the most sensitive of all the tissues of the body to the action of the Roentgen rays, and that these organs can be seriously affected without producing visible effects on the overlying skin. It is likely that the results referred to in this paper are chiefly due to this special action of the rays on the ovaries, and secondarily to their direct effect on uterine fibromas, the uterine tissue, and malignant cells, when present.

If the activities of the ovaries send out a stimulus to prepare the mucous membrane of the uterus for the reception of the ovum, and the degree of this stimulation governs the menstrual flow, then the depression of this function will decrease the menstrual flow and finally lead to its obliteration. This lack of congestion and nutriment probably leads to an atrophy of the fibroids. By decreasing the hemorrhage, at least such pains as are due to the expulsion of the clots will be relieved, and by decreasing the functions of the ovaries there is probably a decrease in the irritability of the nervous mechanism of the ovaries, thus bringing about, consequently, a relief in the dysmenorrhea of neurotic subjects.

Saretzky,⁸ in a series of experiments on sixty-two rabbits, found the ovarian tissue to be especially sensitive to the rays, and, of the ovarian tissue, the ripe and ripening follicles were first affected. Only the weakest dose showed no effect. Progressively increasing doses affected, in proportion to the quantity of treatment, first the ripe and ripening follicles, then the pre-follicular cells and, finally, the interstitial tissue.

At certain stages he found that a beginning atrophy of the follicles undergoes a regeneration, the ovarian tissue develops anew and the ovaries entirely regain their functions. If the treatment is persisted in, however, a complete atrophy takes place. He found that if only one ovary was treated, the other ovary and the entire genital tract retained their normal functions, and the animal was capable of reproduction.

Based on these theories and experiments, we easily find the explanation of the fact that, as we approach the menopause, the quantity of treatment needed to produce sterility and an artificial menopause is very much less than is needed in younger patients in whom the functions of the ovaries is very much more active, and the resistance greater. The resistance of the ovaries in younger people is sometimes remarkable, and on this account the Roentgen-ray treatment is not

the method of choice in patients under 40 years of age. One patient, aged 34, whom I treated over the spleen and abdomen for chronic cyanotic polycythemia and who received a great deal of treatment over the pelvic region during two and a half years, became pregnant and gave birth to a healthy child who is now 4 years old.

Good results of roentgenotherapy, as given by Albers-Schonberg in 1909 and confirmed by myself and many others, are as follows:

1. A cessation of the menses, and associated with this (a), a decrease in the size of the myomas; (b) a decrease or cessation of the hemorrhage associated with myomas, whether it be menstrual or intermenstrual; (c) a disappearance of the pains associated with myomas; (d) a cessation of preclimacteric hemorrhages or pains, whether due to myomas or not; (e) sterilization when indicated.

2. The obliteration of postclimacteric hemorrhage.

3. Disappearance or healing of myomas unassociated with bleeding, such as occurs after the menopause.

4. The control of menstrual disturbances at any age, at times without sterilization and, when necessary, with sterilization.

INDICATIONS AND CONTRA-INDICATIONS

The treatment of uterine hemorrhage by means of the Roentgen rays really consists in the treatment of the causes of the hemorrhage, and, I believe, of first importance, is a careful diagnosis made by a competent gynecologist or by one who is capable of making an accurate diagnosis. There is still some difference of opinion as to the indications and contra-indications for treatment. Those who are most skilful, and who have had most experience, are generally most enthusiastic. As a result their indications cover a wider field, and the contra-indications are fewer.

Indications in Hemorrhages Due to Myomas.—1. All cases of myoma in older women in whom there is already a well-advanced anemia, which may be the cause of an anemic heart. 2. All elderly and young women with myomas, in whom there is marked organic heart-disease, diabetes mellitus, chronic nephritis, marked lung-disease and goiter with cardiac symptoms. 3. All patients beyond the age of 40, in whom there is no contra-indication to the treatment. In general, the older the patient, and the nearer she has approached the menopause, the more prompt and satisfactory will be the result. Under 40, roentgenotherapy is not the method of choice, but good results can be obtained, though the younger the patient, the more treatment will be required. 4. The intramural, or the interstitial variety of tumor gives the best results.

Contra-Indications.—1. All cases of myomas in which the tumor is pedunculated, or which can be excised without destroying the reproductive powers of the patient. 2. Fibroids that have undergone malignant degeneration, or that have become gangrenous, should not be treated. 3. Fibroids associated with disease of the adnexa. 4. Fibromas which are producing such marked symptoms that the patient is endangered more by waiting two or three months for results of roentgenotherapy, than by the result of an operation.

RESULTS TO BE EXPECTED IN THE TREATMENT OF FIBROIDS

The decrease, or cessation of the hemorrhage, is the first result to be expected. The effect is more

prompt the older the patient, or the nearer the menopause has been reached. Generally there is a decrease or cessation of the flow within a month or two after the first two series of the application of the rays. At times, after the first series of treatments, there may be an increase in the hemorrhage; in fact, the two subsequent menstrual periods may at times be increased. Generally, the first menstrual period following the first series of irradiations is not decreased and is at times increased. The second period, which usually follows the second series of irradiations, is usually diminished and the third menstrual period commonly disappears. The increase in hemorrhage following the first series of irradiations, is due to the stimulating effect of the rays on the cells. Following this the vitality of the cells is depressed, and finally destroyed. Increase in hemorrhage is more often observed with the subserous variety of fibroids, and in patients who are very anemic. Therefore, when one begins treatment in this class, there should be a special effort made to place the patient in bed following the treatment, and the attending physician should be prepared, if necessary, to tampon the vagina. In none that I have treated has this been necessary.

In patients beyond the age of 40, there are usually required from three to six series of irradiations given in from three to five months. The number of series will depend somewhat on the number of doses, or amount of treatment, given in each series. In patients under 40, considerably more treatment will be needed than in the older patients, and at times it seems only possible to stop the intermenstrual flow, and restore the menses to a normal quantity. At times the cessation of hemorrhage is almost miraculous. In one patient, the bleeding, which had been constant, stopped after the application of one full dose. With the establishment of permanent amenorrhea or an artificial menopause, the patient is likely to have the same group of symptoms which occur with a normal menopause. They are more likely to occur if the menopause has been produced rapidly. In my cases only three patients complained of such symptoms as flashes of heat, a dull headache and restlessness.

With the cessation of hemorrhage, the general health improves, the patient regains color, weight, strength and appetite; sleep improves and the hemoglobin and red corpuscles increase to nearly normal. Albers-Schonberg urges most strongly that each patient have a record made, at the beginning of treatment, of the amount of hemoglobin and the weight. Both the hemoglobin and the weight should be recorded repeatedly during the course of treatment, for if there is no increase in the weight and hemoglobin, he thinks we are justified in understanding that the case is not purely one of myoma, but should always make one suspicious of a malignant disease. One must, of course, bear in mind that other conditions than that of malignancy may be the cause of loss of weight, and it is only when one cannot account for the loss of weight by any other means, that it should be attributed to a possible malignancy.

The tumor is usually the last to show any effect. Occasionally it decreases in size before the bleeding ceases. Generally there is a decided reduction in the size of the tumor at the time of cessation of treatment, and the reduction continues from this time forward. For instance, if the tumor extends to the umbilicus at the time of beginning of treatment, at the end it may be the size of an orange. The tumor continues to

decrease in size long after the cessation of treatment. In one case, the tumor originally extended to the umbilicus. At the end of two years it was the size of an orange, and at the end of five years had disappeared. In another case, the tumor originally extended to the umbilicus. At the end of two years it was very much reduced, and at the end of four years it could not be found. In 75 per cent. of my patients who have ceased treatment, the tumor has disappeared. With a decrease in the size of the tumor, the pressure symptoms disappear.

The question of malignant degeneration subsequent to this treatment, has been raised. No such case has been observed.

The relief of pain will depend in great part on its cause. If it is caused by pressure of a large fibroid, the pain, of course, will not be greatly relieved until there is sufficient reduction in the size of the tumor to release the pressure. If the pain is due to hypersensitive ovaries or ovarian excitability, it will be relieved comparatively early, because the earliest effect of the rays is shown on the ovaries. Such conditions sometimes exist in dysmenorrhea. The relief of pressure symptoms, such as constipation, swelling of the lower extremities, irritability of the bladder, etc., will, of course, await the reduction of the size of the tumor, and, since this is the latest effect to be seen, it may persist for several months after beginning treatment.

HEMORRHAGES DUE TO MALIGNANT DISEASE

Some good results have been recorded from the treatment of malignant disease of the uterus. I began the treatment of malignant disease of the uterus thirteen years ago. In the first patient I apparently obtained brilliant results, with complete disappearance of the disease, which at the beginning was an ulcerating mass filling the entire pelvis, hopelessly inoperable. The patient returned to the hospital one year later for the treatment of a severe Roentgen dermatitis, or degeneration. At this time there was no evidence of malignant disease in the pelvis.

Following this I treated, in all, fifteen cases. All were inoperable or recurrent. In all I got some reduction in the hemorrhage and some improvement in the general symptoms, but, in the end, all the cases but the first case were failures. During the subsequent eight years I then refused to treat such cases, but during the past six months I have taken new courage and enthusiasm from the general results obtained in deep roentgenotherapy.

I have under treatment now, five recurrent cases, following hysterectomy. In all there has been some improvement, some reduction or disappearance of the bloody discharge, relief from pain and improvement in the general health. One seems to have gotten well. In one other case there was no improvement, and the patient died about six weeks after the first and only series of treatments, from ulceration into the bowel. The attending physician believed that this was only the natural course of the disease and not due to the treatment, for there was no damage to the skin.

At the International Congress at London, 1913, Kroenig referred to ninety-six cases of carcinoma of the uterus which had been treated with radium and Roentgen rays, radium being used for the local effect and the Roentgen rays used over the abdomen for the general effect. In forty-six cases of these, the lesions were healed. The longest period of healing, however, had only been one and one-half years.

A review of the twenty-one cases treated by Albers-Schonberg (reported at the International Congress at London, 1913), shows encouraging results, but he feels that several years must pass before we can draw any accurate conclusions.

In general, while we now have some encouragement in the treatment of malignant disease of the uterus, it is not sufficient to justify us in recommending it to replace operation. We should, therefore, urge immediate operation in all cases in which the diagnosis is made while in an operable stage.

For the present we should only recommend roentgenotherapy in the inoperable and recurrent cases. While such cases are correspondingly more difficult, and, therefore, our statistics equally poor, we can hope to do some good in all, and each patient that recovers is just one more saved from the grave. It is to be hoped, however, that such patients will be referred immediately and not allowed to progress for months, and then in the terminal stage sent with the hope that a miracle can be performed.

I believe, too, that the results that have been obtained in the treatment of deep-seated malignant disease justify the surgeon in recommending post-operative roentgenotherapy in all cases operated on. This treatment should be given as soon as the patient can be safely removed to the laboratory. It should be given vigorously, but carefully and skilfully. The possession of Roentgen apparatus is no more a guarantee of skill in roentgenology than is the possession of surgical instruments a guarantee of skill in surgery.

METROPATHIC HEMORRHAGE

Under this heading Eymer and Menge include the following:

1. Cases of bleeding connected with disease of the uterus in which there is no tumor or none recognizable, cases of so-called "metritis."
2. Cases of hemorrhagic endometritis.
3. Climacteric hemorrhages, which are not malignant in origin. In this class of cases deep roentgenotherapy has accomplished good results, and is especially indicated.

Roentgenotherapy has also accomplished good results in some cases of hemorrhage connected with inflammatory disease of the adnexa (Menge), and is indicated in those cases in which operation is contra-indicated for some reason or other.

TECHNIC

In general, the object of the treatment is (1) to depress or obliterate the functions of the ovaries, thus producing an amenorrhea or oligomenorrhea; and (2) to cause an atrophy of fibroids, if present, (a) by action on the ovaries; (b) by direct action on the tumor; (3) to cause degeneration of the carcinoma cells, which should be replaced by healthy connective tissue; and (4) to restore the bleeding mucous membrane in the metropathic cases, to a normal or healthy condition. This should be accomplished without damage to the skin, the bowels or the lymphatic glands, with a fair degree of certainty and within a reasonably short time. Therefore, the greatest attention must be given to technic. To learn this technic, one must learn the principles of roentgenography, as well as roentgenotherapy. This technic is not easily learned, or more men would know it.

The exciting instrument should give a uniform current of high voltage, and sufficient in quantity to excite

any given tube to a high degree of efficiency. Previous to the development of the Coolidge tube, I preferred the high-power, high-speed static machine, 40 plates. Since the development of this new tube, which marks a wonderful advance in roentgenotherapy, I prefer the transformer type of inductor having a rhythmur attachment, which I believe gives the greatest degree of efficiency, and enables one to give a dose in the shortest period of time. In using this very powerful type of equipment, however, special skill is necessary or harm will result. In general, any type of exciting apparatus can be used if the proper balance is maintained between the amount of current used and the proper degree of penetration of the rays from the tube, with a corresponding duration of the treatment. Therefore, the induction coil, transformer type of inductor or the static machine can be successfully used.

The tube should be one that will keep a constant high vacuum of from 7 to 8 Benoist. If the tube is allowed to get soft, the rays will be absorbed in the superficial tissues, resulting in a burn, and the deep effect on the ovaries will not be obtained. Since the development of the Coolidge tube and one or two other recent types, it is possible to adjust the degree of vacuum at will and maintain it uniformly, at the same time using a large quantity of current.

The most practical distance of the target of the tube from the skin of the patient, with our present type of holder and present shape of tubes I have found to be 8 inches. Later, I think we shall develop apparatus which will permit us to get nearer and so to get a greater quantity and more divergence of the rays, which will pass through the small area of skin.

The field of application of the rays is over the diseased area, and in the case of fibroids should be especially directed toward the ovaries, and include the fibroid from every possible direction. The rays should be confined to the area treated as much as possible. If a rapid result is desired, large doses must be given, and since one must not exceed the tolerance of the skin over any particular area, the field of application must be subdivided in such a manner that, by cross-firing an increased dose will reach the deep tissues without affecting the skin. It is this subdivision of the skin-area which has permitted the large doses especially referred to by Gauss and Lembcke and usually spoken of as the Freiburg technic, in which they aim to give all the treatment necessary at one time. This is the other extreme of the swing of the pendulum, as compared with the often repeated, very small doses which were first used by myself and others. It has, however, landed the more conservative man into the middle-road technic, which consists in giving full doses through a number of fields at one time rather than often repeated small doses through the entire lower abdomen, scattered over a long period.

The Freiburg technic is very often spoken of in contradistinction to the Hamburg, or Albers-Schonberg technic. It must not be forgotten, however, that all the prominent roentgenologists are progressive, and what was referred to as the Hamburg or Freiburg technic a year or two ago, is not referred to as the Hamburg or Freiburg technic of to-day. The leaders of both these centers have come closer to a middle course. Albers-Schonberg, like the rest of us to-day, divides the area into a number of subdivisions, and the leaders in Freiburg are making much fewer subdivisions. At present I am guided by the size of the abdo-

men, the depth of the tissues to be treated and the extent and the nature of the disease. For instance, if I am treating a small fibroid which is entirely in the pelvis and is in a thin patient, the subdivisions and fields for the entrance of the rays can be at a minimum, and good results can be obtained by giving a series of treatments through three fields anteriorly and one field in the perineal region. On the other hand, if the fibroid is large and the abdomen thick, I commonly divide the area into twenty-five or more doses, and in carcinoma of the abdomen I at times treat through thirty-five or forty subdivisions, giving the limit of skin tolerance through each area. So, too, when one is dealing with malignant disease or when one is very anxious to produce very rapid results, the quantity of treatment given in any particular series must be correspondingly increased, and, in order to increase this total dosage, the number of points of entrance of the rays must be correspondingly increased. Generally, in the treatment of fibroids, I believe it is not desirable to bring on a very rapid menopause, for by producing this change gradually, there is given an opportunity for the system to accommodate itself to the change.

Albers-Schonberg⁹ has expressed very well the present guiding principles that should govern us in the quantity of treatment, in saying that only such a quantity of rays should be applied as is necessary to produce a satisfactory result, uninfluenced by the duration of the treatment. One can readily see, therefore, that in principle, his ideas are similar to mine—that careful judgment should govern us in each particular case, and that a general rule is no more applicable to all cases in this treatment than is a general rule applicable for an operation to suit all cases.

The time required to give any particular series of treatment will depend on the character of equipment and the technic of the individual operator, as well as on the condition and circumstances of the patient. Generally I use one, two or three days to give any series of treatments, depending chiefly on the number of doses that have to be given in a series. The total dose given in any series varies from 40 to about 800 X. The interval between any series of treatments should not be less than two weeks, and I believe more safely, not less than three weeks.

In one case, in which the malignant disease had matted together all the abdominal viscera, as found by an exploratory operation, I repeated the treatment in two weeks, and in several areas obtained a severe dermatitis. Fortunately, however, these skin ulcerations are practically healed, and the malignant disease in the abdomen, so far as I can tell, has disappeared.

The favorable time for treatment is immediately after a menstrual period. When one has a choice in the matter, the treatment should at least be given ten days before the beginning of the succeeding period. If the bleeding is continuous, the treatment should be given just after the time that would correspond to a period. The skin dose, or total quantity of rays applied to the surface should be carefully measured so as to avoid burns.

A dose refers to the amount of rays that the skin will tolerate without producing more than a slight erythema. This dose, measured by the Kienbock quantimeter, is referred to as 10 X. Measured by the Sabouraud and Noire pastiles or disks, it is recognized as Tint B; or, measured by the Holzknecht radiometer,

it would correspond to 10 units. As referred to in the general literature, the units 10 X (Kienbock) or 5 H. (Holzknecht) correspond to an erythema dose, given without filtration. With filtration, this dose, when measured under 3 mm. of aluminum, can be increased to from 20 to 30 X. To do this, however, one must have a tube that is giving uniform rays.

Filters should be used to cut off the rays that are mostly absorbed by the skin. For this purpose the leather filter, first recommended by myself,¹⁰ has served well. On top of this I now add for this deep roentgenotherapy, 3 mm. of aluminum, and I place these just above the diaphragm of the tube stand.

At present I am giving a dose of 30 X through each area treated. I am not prepared to recommend this extremely high dosage for general use, and would like to add a word of caution to anyone who has not thoroughly mastered his own technic. Therefore, when I treat a case through four fields, it means that the patient is getting 120 X. If the patient is treated through 30 fields, it means 900 X. In this connection I would like to add what Albers-Schonberg has already said, that no case should receive more treatment than is necessary to produce permanent results, and without regard to the speed with which these results are to be obtained. In the treatment of malignant disease, one must use enormous doses to accomplish results.

Skin effects, in the hands of skilful operators, have been of almost no consequence. In a number of patients treated an erythema developed, and in others the skin became pigmented or tanned. These effects disappeared, leaving the skin undamaged. In a few cases a dermatitis of the first degree has been produced. In these later cases telangiectases develop in the skin about a year later. In the treatment of malignant disease, skin irritation is of secondary importance, but one should never go beyond the production of a slight erythema.

DISADVANTAGES AND ADVANTAGES OF THE TREATMENT

The disadvantages are the following:

1. The prolonged course of treatment that is usually necessary. This can be somewhat shortened by giving enormous doses through a large number of fields. If by this means the course of treatment is reduced to two or three months, it will probably only equal the time required for operation and convalescence therefrom.

2. There is danger to the overlying tissues, if the rays are not properly applied. By careful attention to the technic and exact measurements of the skin dose, this can be eliminated.

3. It has been claimed to be more expensive than operation. In a sense this is true. If one considers, however, that by this treatment the expense of board and hospital care is eliminated, both in the case of charity and private patients, and that in both instances they can go about their usual duties, I believe we must conclude that it is not more expensive.

The advantages are:

1. It is painless.
2. It avoids the shock of an operation.
3. It preserves to a certain extent, we believe, the internal secretion which is lost in a complete oophorectomy.
4. It does not interrupt the usual habits.
5. Confinement in a hospital is avoided.

9. Albers-Schonberg: Tr. Sect. Radiology, Seventeenth Internat. Cong. of Med., London, 1913.

10. Pfahler, George E.: Tr. Am. Roentgen-Ray Soc., September, 1905.

6. In the hands of a skilful operator it is without risk.

7. The menopause is brought on gradually, when necessary.

8. The amount of treatment can be graded to the needs of the patient.

1321 Spruce Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. NOVAK, KELLY AND PFAHLER

DR. CHARLES C. NORRIS, Philadelphia: As I view the subject it is largely one of the study of etiology—in other words, to treat uterine hemorrhage intelligently we must be cognizant of its cause. Uterine hemorrhage is a symptom and not a disease, and no rule of thumb can be successfully employed in its treatment. If any criticism whatever can be applied to the excellent papers comprising this symposium, it is that this point has not been sufficiently dwelt on. Each case must be studied and treated individually. Some of the chief causes of hemorrhage are myomas and carcinoma of the uterus, endometrial polyps, hypertrophic thickening of the endometrium, displacements, adnexitis, ovarian neoplasm, disturbances of the functions of the various ductless glands, especially the ovary, certain constitutional diseases, especially syphilis, tuberculosis, hemophilia, chronic liver and heart, kidney and lung disease, besides other less frequent conditions. When we consider the great number of diseases which may cause hemorrhage, the importance of accurate diagnosis is apparent. As an example of this I may cite a case in which I was recently asked to perform a curettage for hemorrhage on a patient suffering from syphilis. The pelvic examination was negative and the exhibition of neosalvarsan checked the hemorrhage very quickly. A curettage in this case would have been of no benefit. The constitutional disease was what required treatment. The treatment of myomas of the uterus with radium or Roentgen rays undoubtedly has a very definite place in gynecology. No one however skeptical can fail to be convinced by the excellent results reported by Drs. Kelly and Pfahler, as well as those by Krönig and Gauss and others. Personally, however, I doubt very much if the Roentgen rays or radium will ever supersede surgery in the routine treatment of uterine myomas. The extremely small operative mortality and the excellent postoperative results are strong arguments in favor of the surgical treatment, whereas the prolonged treatment required and the expense, as well as the somewhat less certain results, are points that must be considered before Roentgen-ray or radium treatment is selected. Another important point of practical value is that carcinoma of the fundus is occasionally and indeed relatively frequently an accompaniment of myoma of the uterus. In all patients suffering from hemorrhage at or near the cancer age it is our first duty to exclude carcinoma, and this is particularly true in those cases in which the pelvic examination is negative or reveals only a slightly enlarged uterus. Dr. Kelly, you will remember, has very properly performed a curettage for the purpose of determining this point as a preliminary step before instigating the radium treatment. In closing I would again urge the necessity of studying the etiology of each individual case, for only by so doing can the proper treatment be instigated.

DR. JOHN A. MCGLINN, Philadelphia: So far as the nervous element of the bleeding from the uterus is concerned, it is not so much due to shock to the nervous system as it is to the result of the shock on some of the ductless glands. In the few cases following shock I have noticed other metabolic changes, such as falling of the hair and change in menstrual bleeding. Some time ago I sent out a letter to the members of the American Surgical Society asking whether in their opinion surgery could be eliminated in the treatment of fibroid tumors of the uterus. Eighty replied that positively it could not be. The same question was asked the Roentgenologists and eight out of 90 replied that it could be and that the Roentgen ray should take the place of surgery. I feel that we should not confuse the cure of fibroid tumors of the uterus with the relief of bleeding from fibroid tumors of

the uterus. I have no quarrel with radium or with the Roentgen ray, but that surgery can be eliminated in the treatment of fibroid of the uterus I do not believe. I believe that even with the Roentgen ray and radium, surgery is still the best treatment. The mortality of surgery in these cases is due to the various complications present other than sarcomatous degeneration; so that, considering the mortality, it will be found that the Roentgen-ray treatment has not a great advantage over surgery, taking into consideration the ultimate cure. The reports given by Dr. Kelly are amazing. According to the reports gathered in the clinics in Europe, but 5 per cent. of the tumors entirely disappeared. That simply means that 95 per cent. of these tumors are in a condition to undergo complications which will bring the high operative mortality; whereas, if the cases were treated by surgery, even if 5 per cent. of the patients do die, at least 95 per cent. of the cases are cured against 5 per cent. cured by the Roentgen ray.

DR. WILLIAM S. NEWCOMET, Philadelphia: I am glad to know that when Dr. McGlinn sent out that little note, only eight out of one hundred roentgenologists decided that all tumors could be treated by the Roentgen ray. As a rule I think that roentgenologists try to be conservative, and this proportion shows well for our work. The work of Dr. Kelly and Dr. Pfahler shows that under these good reports was skill. No doubt the great trouble often in the matter of results is that many patients are treated by persons who do not understand how to use these methods. Furthermore, I am glad also to hear Dr. Kelly mention the fact that the Roentgen ray and the gamma ray are not to be regarded the same. It was twice stated in this meeting by men in other Sections that the Roentgen ray and the gamma ray are identical and that they can be used one for the other. Any one who has ever had any experience with the Roentgen ray and with radium and has seen the reaction from each, must be impressed with the entirely different process following the application of either of these methods. Also if you should have a burn or a reaction from the Roentgen ray in the same proportion as you have a reaction or burn from radium you would have a lifetime injury; whereas the reaction from radium will clear up in a very short time. It is a curious thing that abscess follows the destruction of tissue in these cases from radium. Dr. Kelly has referred to this, and I have seen it twice in my own experience. On the other hand, it is very rare to have abscess follow destruction of tissue from a Roentgen-ray burn. Dr. Kelly's results exceed any I have seen so far published. They far exceed those of the London Radium Institute, which I am in the habit of quoting because I think they are given from a very conservative basis. Another important point taken from Dr. Kelly is that his applications are directly on the tumor, while in the vast majority of cases treated by the Roentgen ray, the influence on the fibroid is from the reaction on the ovary. Curiously enough, it has been cited time and time again that in these pelvic cases treated by the Roentgen ray sterility usually follows. About ten years ago I treated for Dr. George Erety Shoemaker a patient with a large sarcoma of the pelvis about the size of a seven months' pregnant uterus. The woman recovered and became pregnant twice, the first pregnancy occurring two years after the disappearance of the tumor. The woman is now in good health.

DR. STEPHEN E. TRACY, Philadelphia: Before we can intelligently treat a case of uterine bleeding it is necessary to make a diagnosis, and this is not always possible before operation. I cannot speak of radium, as I have had no experience with it, but I want to congratulate Dr. Kelly on the wonderful results. There are those who assert that all cases of carcinoma of the uterus and all fibromyomas of the uterus should be treated by roentgenotherapy, and I trust that Dr. Kelly in closing the discussion will state his position in this matter. Dr. Pfahler has designated what cases of uterine bleeding are suitable for roentgenotherapy, and I believe that most of us will agree largely with his statements. We all know that Roentgen-ray treatment for malignant disease of the female pelvic organs has been practically worthless. In regard to fibromyomas of the uterus, it is well known that malignancy is present in from 4 to 5 per cent. of the cases. Malignancy and the

various other degenerations of fibromyomas of the uterus are found in 15 per cent. of the cases which come to operation, and such cases are not suitable for roentgenotherapy. When we add to this 15 per cent. the complications and associated conditions in the appendages, we have in between 30 and 35 per cent. of the cases conditions which would not be cured by roentgenotherapy. At least 25 per cent. of the women with fibromyomas of the uterus who have come to operation, would have perished, sooner or later, if they had been relegated to the roentgenologist. It is generally conceded that women under the age of 40 years are not good subjects for Roentgen-ray treatment. It has been clearly shown that after the age of 40 years the dangers of fibromyomas of the uterus increase with advancing years. In a collected series of approximately 700 cases I found that 70 per cent. of the degenerations took place in women after the age of 40 years, and that over 90 per cent. of the malignancies were found after that age. When all these facts are considered, the conclusion is inevitable that the best treatment for the majority of these tumors which produce symptoms is early surgical intervention, unless Dr. Kelly can cure them all for us with radium.

DR. CURTIS F. BURNAM, Baltimore: I have been studying with Dr. Kelly the cases reported. I have seen them from the very beginning and therefore have taken a very lively interest in the foregoing papers and the discussions. I incline to believe that many cases of uterine hemorrhage are really dependent on uterine and not ovarian conditions. This view is partly substantiated by a series of cases in which I operated on young girls for hemorrhage; curettage having failed to relieve them, resection of the ovaries was finally resorted to. In spite of the reduction of the ovaries the bleeding continued. In one of the group intra-uterine application of radium brought about a return to normal menstruation after operation had failed. An interesting point in connection with all these cases is the frequent absence of menopausal symptoms when complete amenorrhea has been produced by the treatment. It is quite astonishing to interview a patient who gives no history of menstrual or other bleeding and yet reports not the slightest general disturbance. Proceeding to the therapeutic questions involved in these cases, I should like to be put on record with Dr. Kelly in asserting definitely that the ray treatment will perhaps entirely replace operative surgery and will certainly do it in most cases. The treatment itself is extremely simple, without danger, is not time-consuming, and in no way prevents going on later to surgical methods if it proves unsuccessful in any given case. I should like also to say in reply to one of the speakers, that the recent reports from Freiburg of mesothorium treatment in similar conditions in every way conformed to these results here reported. Gauss and Lempke state that in sixteen fibroids radiated, fifteen have entirely disappeared and one greatly decreased. I should like also to emphasize that the effects of radiation in uterine fibroids, as also in polypoid endometritis, and perhaps also in cases of metrorrhagia hemorrhagica should be on the tumor and uterus and not on the ovaries. So far as I know no one has treated a large fibroid tumor of the uterus in which the growth disappeared within a few months after radiation and the patient continued with normal menstruation up till the cases which we report. The efforts of most European roentgenologists have been directed toward devising technic to radiate the ovaries. It has been assumed that the effect on the fibroid is indirectly through the ovaries, although many have stated that there may be an effect on the tumor itself. Our plan is to protect the ovaries and radiate the tumor. Under radiation the tumor disappears rapidly; from ovarian ablation the disappearance is slow, extending over months and years. Radium has the advantage over the Roentgen ray because it is applied inside the uterus, affects directly the tumor and to a lesser degree the ovaries. It would seem easily possible, however, to devise a technic for the Roentgen ray which will radiate the uterus and not the ovaries. I am far from saying that in a very short time results as rapid and complete cannot be gained by the Roentgen ray as well as by the radium. In polypoid endometrium amenorrhea cases cessation of bleeding was brought about immediately from the day of the treatment.

DR. GEORGE ERETY-SHOEMAKER, Philadelphia: I have a word to say on the subject of any treatment which leaves the tumor in the pelvis, when there is a tumor. The complications are often more important than the tumor and bleeding is the only one of them which may be modified by the Roentgen ray. Dr. Pfahler in his interesting paper mentioned that the question of malignant degeneration had been raised but that no case had been reported. I had the experience two months ago of operating in a case to be later more fully reported which had been under Roentgen treatment by a competent operator for fibroid tumor, but which later developed sarcoma. The whole treatment by other means than hysterectomy went through seven years, first, for a year by the active electrical treatment which we no longer hear about. Then the patient had Roentgen treatment twice a week for many months and the hemorrhage stopped, as it does in some fibroid cases. She still shows purplish spots in the skin over the abdomen, due to the Roentgen ray. After five years of cessation, her tumor increased in size, she began to bleed again, and her physician, Dr. Evans, sent her to me for hysterectomy. She had a fibroid tumor of the uterus with sarcomatous degeneration scattered in various parts through it. After years of treatment she had to have the operation after all. In Dr. Kelly's series of polypoid endometritis case there is one confusing element. He says he curetted each one before the application of radium. Of course the curet alone will in good hands stop the hemorrhage in a certain number of cases. According to his table some of the patients had not previously been curetted.

DR. GEORGE C. JOHNSTON, Pittsburgh: Dr. Kelly states that he has taken the opportunity to bring this matter before the general profession through the medium of this meeting and through the medical press. In regard to the Roentgen-ray treatment of fibromas, I am surprised at the attitude taken by some of the profession. We roentgenologists do not wait to treat these cases. Our position is this: we are engaged in our work, and in walks a prominent gynecologist. He says "Don't you see what they are doing over in Freiburg?" We perfect our technic and devote ourselves to this work and then we are blamed for taking these cases. We do not want them but if you men will not take them, we shall be obliged to. We will treat only those cases that are referred to us by competent gynecologists who say that in their opinion these cases are better treated at the hands of a competent roentgenologist than by the surgeon.

DR. EMIL NOVAK, Baltimore: In the present state of our knowledge it is unwise to be dogmatic as to the relative importance of the uterus and ovary in the causation of functional uterine hemorrhage. Even though it be shown that uterine bleeding is caused by a local factor in the endometrium, it seems probable that the presence of this factor is in some way due to the activity of the ovary. The assumption that there is a local physiologic disturbance in the endometrium would seem to explain why curettage will sometimes relieve uterine bleeding, even though the removed endometrium is microscopically normal. In these cases it is unlikely that the cessation of the bleeding is due to the removal of the accumulated coagulation-inhibiting substance in the endometrium. As I stated in my paper, anatomical changes in the endometrium are often, no doubt, the result rather than the cause of menstrual aberrations. We must learn to look on the endometrium as a sensitive plate which registers the more fundamental phenomena of menstruation. Certain histologic changes are now recognized as characteristic of the normal menstrual cycle, and in the same way we must learn to appreciate that various histologic pictures, abnormal as to degree or time of appearance, may be encountered when menstruation is abnormal.

DR. JOHN M. FISHER: I want to ask Dr. Kelly whether the fibroid tumors were selected cases?

DR. HOWARD A. KELLY, Baltimore: The fibroid tumors were not selected in this series. If I had any extensive abscesses or cancer of the body complicating the fibroid I would not use the radium, but would take any other case that came along. In hemorrhage cases and the fibroids with or without hemorrhage, the first thought is radium and not operation.

ation. Curettage was done at the time the patients were treated. Many of them had been curetted previously but unsuccessfully, or they would not have come into our hands for treatment for the hemorrhage. It is an entire innovation in our methods and in the matter of the benefit of the patient. The operative cures of sarcomas of the uterus are practically nil. In about 400 cases treated with radium and Roentgen rays in Freiburg there is no case on record with history of subsequent development of malignancy. In illustration as to the effect in sarcomas: A tall overgrown lad with a big tumor in the left abdomen comes for treatment. After treatment for several months, on examination nothing could be felt through the abdomen but a small mass through the rectum. Dr. Burnam took that out and it was found to be a testicle which had become sarcomatous. On the other side there were two fallopian tubes and a little uterus in between. In other words, it was a case of mixed sex elements. Something new has come into our midst and something big. We must take hold of it and see what comes of it. We are using radium every day for uterine hemorrhage, for fibroid uteri. We have radiated many carcinomas of the cervix uteri. In some cases we have later removed the uterus. In not one have we discovered any cancerous elements remaining. In one of them we found some of the pelvic lymphatic glands infected. In one case we found the glands enlarged at the operation. We have a very definite hope that we can follow these cases in a considerable series. A number of cases come to us with other ailments, such as Bright's disease, diabetes and carcinoma of the uterus, which cannot be operated on. Some have profound anemia; others tuberculosis. To all these cases radium comes as a great boon, which is going to be extended and which we hope to develop in this class of cases. It does not take such a large amount of radium that the slender pocketbook cannot afford it.

DR. GEORGE E. PFAHLER, Philadelphia: I want only to answer one or two points, one with reference to the disappearance of the tumor. I said that 75 per cent. of the tumors I had treated had disappeared, and so they have, and you must not forget that these quotations made by Dr. McGlinn are mostly based on the work of men of few years of experience. They have treated more cases than I have. The roentgenologists have been working for from eight to ten years, and that is the reason we can speak with a little greater emphasis than these men can, because the tumor continues to disappear long after the treatment has stopped. With reference to degeneration of the tumor, I inquired of the physician who treated the patient referred to by Dr. Shoemaker. The patient came weekly for treatment through the years when the treatment was much less developed than at present. He referred the patient for operation. Regarding degeneration of these tumors, it has been stated by men who know that 5 per cent. undergo malignant degeneration. If this is true, why have not 5 per cent. of those treated undergone degeneration? And if they have, do you believe that the physicians of this country have so neglected their duty that they will not call the attention of the profession to the fact that these tumors undergo degeneration later? Until we have definite data we have no right to assume that these tumors will undergo subsequent degeneration.

Insects and Disease.—When the history of medicine during the past quarter of a century comes to be written, the one outstanding feature of the period will be shown to be "the part played by insects in the spread of disease," and the application of this knowledge as a practical hygienic factor. Vermin have been "detested, shunned by saint and sinner," since the creation of man, but the reason for the abhorrence has only been proved of late years. That the mosquito can carry malaria, yellow fever and filaria; and that the bedbug, the louse, the flea, the fly, the blackbeetle, the tick, the itch insect and other vermin are agents in the transmission of a given disease is now common knowledge. This information has placed the subject of domestic and public hygiene and sanitary endeavor on a sure foundation, and given a stability to preventive measures hitherto unattainable.—*Jour. Trop. Med. and Hyg.*, April 15, 1914.

AN UNUSUAL CASE OF BROMODERMA OF THE LEG*

LUDWIG WEISS, M.D.

Consulting Dermatologist Hebrew Orphan Asylum, Saint Mark's and People's Hospital, Chief of Clinic of Genito-Urinary and Dermatological Department, German Poliklinik

NEW YORK

Of the three halogen elements which play such a great rôle in the household of nature, bromin, discovered by Bayard in 1826, is the youngest. The others are iodine, discovered by Schele in 1774, and chlorine by Curtois, in 1812. English and French physicians were the first to use bromin and to study its action.¹ In Germany Otto Graf (1840) emphasized its sedative and depressant action on the nerve-centers. But it remained for Sir Charles Locock to introduce it in 1851, and to acquaint the profession with its main therapeutic virtues. Its position at present is that of a neuromuscular depressant and as such its main use, logically, is directed against the best-known of all convulsive diseases, epilepsy. Inasmuch as in potassium bromid the acid bromin, as well as the base potassium, has a sedative active on the nerve-centers and on the muscles, the salt is eminently fitted to cope with the explosive attacks of epileptic convulsions and hence is the most widely used of the numerous bromid compounds. It is excreted by the kidneys more rapidly than other compounds because of double decomposition in the blood, with the formation of potassium chlorid, which acts as a diuretic and increases the chlorine excretion through the kidneys. While small doses administered for a long period cause blunting of the sensory nerves, impairment of motor and diminution of reflex activity, continued large doses will cause the more pronounced depressive attacks known as bromism.

Fig. 1.—Bromoderma of leg; showing a slightly scalloped border with a few partly healed ulcerations. Lower border ends abruptly in a semi-circular line. Quiescent stage. No active symptoms at present. Leg shows smooth atrophic surface with thin easily detachable scales.

Although, as shown by Kross,² Albertini,³ Nencki,⁴ Fell,⁵ Hoppe,⁶ and especially by von Wyss,⁷ Ellinger⁸ and others, in chronic bromid intoxication the central nervous system has to bear the main brunt of attack, yet the symptoms of bromism are not due to a surcharge by it of these centers, but rather of the blood. It replaces with avidity the chlorine content of the blood and the gastric juice and is found in the secretory and excretory organs.⁹

It has been shown that those organs richest in chlorin contain the greatest amount of bromin, hence blood-serum contains the greatest amount of it, next in order being mother's milk, tears, saliva and the skin. In a regimen of salt-poor diet in animals Von Wyss has demonstrated that 40 per cent. of the chlorids must be replaced by bromids to cause poisoning, and Hoppe¹⁰ found in the gastric secretions of epileptics one-third of the chlorids replaced by bromids when the bromin influence showed itself. The antagonistic effect of these two elements is remarkable. Bromism is caused by the accumulation of bromid-ions and diminution of chlorid-ions in the blood and in all the other body juices and organs. Both conditions, it seems, are interlocking; it may be the plus of bromin or the minus of chlorin that causes the intoxication. When table-salt is withheld from the diet of epileptics they become more susceptible to the action of bromin, while abundant administration of table-salt causes the bromism to disappear by increased kidney activity.

ETIOLOGY OF DRUG ERUPTIONS

These will be encountered chiefly in epileptics as they are the principal consumers of the bromin compounds. Though almost any drug may cause an eruption, yet, for obvious reasons, those caused by the

Fig. 2.—Bromoderma of leg; showing the convex lower border and centrifugal extension of the process downward. Outside aspect of right leg. Also shows some activity yet, as seen in the healing ulceration on the upper border.

iodids and bromids have merited the greatest attention by the profession. The mode of development of these eruptions has hitherto been quite conjectural, but certain observations have brought us nearer to concrete facts, although not to perfect understanding. There are several theories extant concerning the nature and manner of drug eruptions. It is somewhat disappointing that the most natural explanation, the excretion of the "materia peccans" by way of the blood through the glandular system of the skin, is doubted.

Not many facts resting on a solid basis have been adduced to prove modern and fanciful theories. Humoral pathology in modern garb, to which we unconsciously are drifting, offers a plausible explanation. If we substitute the modern toxin for the obsolete "materia peccans" and discard the mysterious "critical sweats and eruptions" by calling them reflex phenomena or vessel changes, then we have a working basis at least approximately serviceable to explain drug eruptions. The general consensus is to call drug eruptions only such phenomena of the skin as follow the ingestion and absorption of certain drugs. Skin lesions produced by the external application of drugs are called artificial dermatitis or dermatitis venenatae.

Their action is due to their irritating properties exerted on the skin, which depend on the strength of the drug; while the drug exanthems *per se* do not generally depend on dosage. Here a predisposition, a so-called idiosyncrasy, must be present, an intolerance, as it were, for the particular drug or food (crabs, strawberries, etc.). But this arbitrary division becomes untenable when we consider that drugs like salicylic acid, antimony, chloral, antipyrin, etc., may cause eruptions when used both internally or externally; while others will not cause eruptions when applied externally, but will when taken internally (strophanthus, rhubarb, etc.). Again, iodoform is taken internally without unfavorable consequences, while externally it causes great irritation in some persons. It is, therefore, impossible to systematize the etiology of drug eruptions. They may be caused in different ways, either through irritation of the skin glands or their vessels in excreting the toxic substance, or through reflex irritation of the vessels.¹¹

On the other hand, external skin irritants like rhus or chrysarobin may cause very intensive constitutional symptoms. The theory of cumulative action, while it fits certain phenomena, does not explain why certain individuals will show a skin eruption very soon after the ingestion of small quantities of a drug which does not harm the great majority of others. Such a predisposition may be a lasting or a temporary one, or one becomes accustomed to skin irritants. With quinin eruptions a hereditary predisposition is observed, while in some instances such abnormal sensitiveness may be acquired and in others become lost. Kaposi¹² thinks that the vasomotor influence cannot hold good in all instances. Some rare cases of urticaria appear as soon as the provoking substance is taken into the mouth. Here the eruption can be explained only by a reflex irritation via the gustatory nerves.

Again the same drug may cause different forms of eruption in different individuals while different drugs will always cause the same form in the same person.¹³ The polymorphism of these drug eruptions is one of the main features distinguishing it from other well-defined inflammatory types which they may simulate, and which are dependent on a functional disturbance of the vasomotor nerves (angioneuroses). For instance, in urticaria *ab ingestis* the toxins generated by the fermentative products from the gastro-intestinal canal act on the vasomotor centers in the same manner as the irritant drug iodine or bromine.

It is, therefore, as stated before, impossible to narrow down all the enunciations of drug exanthems into a system. Neither from the point of view of the drug, nor from that of the different response on the skin is such a generalization possible. We must have recourse to more or less proved theories, namely: an especially vulnerable skin, differences in the anatomic structures or their distribution (vessels, nerves), a peculiar receptivity of the system, deviation from the normal of the position of the skin-glands, secretory and excretory alterations of their functions and many other incidents partly speculative, partly scientifically demonstrable. Predisposition for and idiosyncrasy against a certain drug, food, or external irritant are yet valid as causes but fortunately not the exclusive explanations in this contradictory domain. If I add

to these more or less plausible theories that the skin lesions are caused by the drug itself or its metabolic changes directly or by reflex action via the vasomotor or trophic apparatus, we have in a nutshell all that is known of the causation of drug eruptions.¹⁴ Skin eruptions of a kindred type are observed also after adenoid operations, icterus, serum-therapy, etc.; here the trauma, the bile, the decomposed albuminous products are the causative agents of the skin eruptions.

SYMPTOMS, DIAGNOSIS AND PATHOLOGY OF BROMODERMA

The best evidence that drug eruptions are of angioneurotic character, caused by functional disturbances of vasomotor nerves, is the fact that they simulate almost to the point of confusion other well-known exanthems like erythema nodosum, erythema multiforme, urticaria, scarlatiniform eruptions, etc., known to be of angioneurotic origin; that fever and general systemic disturbances are mostly absent or when present appear only in a mild degree. This forms a distinctive point in the diagnosis of a drug eruption. The differentiation from the infectious angioneuroses—acute exanthems,—will not be a difficult task if we take into account their onset, development, and the highly violent systemic disturbances accompanying them.

Iodin and bromin eruptions have some marked peculiarities which differentiate them from other medicinal skin lesions which show a tendency to appear either discrete or generalized. The two have very much in common and, in cases in which the vitiating drug is unknown, they may present some obstacles to a correct diagnosis. There are certain etiologic as well as clinical and histological features, however, which enable us to distinguish the one from the other in most instances.

The average bromin eruption, as is well known, starts with acne-like lesions in places where acne vulgaris usually appears. In its severer types the base of these papulopustules becomes infiltrated and the lesion appears to be raised above the surface. Soon others will appear and a patch of grouped pustular lesions clustered together become confluent in places, occupying a space the size of a silver dollar or larger. This type usually is found on the extremities, with a preference toward the lower one. This agglomeration is characteristic of bromid eruptions. Through proliferation and hyperplastic changes, tuberculous, furuncular, and anthracoid formations develop which soon break down, forming fungating, papillomatous or ulcerated highly colored elevations, appearing as if a sarcoid had broken down. The borders of these elevations carry small, sieve-like perforations, giving it the appearance of a honeycomb, from which a foul-smelling smegma issues. These conglomerate patches soon become covered with greenish adherent crusts occupying large areas of several square inches, favoring the lower part of the leg, as in the case I will describe; or they may appear in discrete patches all over the body. Phlyctenular eruptions of the conjunctiva bulbi, and furuncular lesions of the external auditory canal¹⁵ have also been observed. I have seen painful furuncles of the follicles of the vibrissae of the nostrils, causing an erysipeloid inflammation of

the alae nasi. Comby,¹⁶ Marzianni and others¹⁷ have seen in infants bromodermas acquired through their mother's milk.

The diagnosis of a bromin eruption, if the cause is unknown, may offer considerable difficulty. Diagnosis of the discrete, acne-like or the papulopustular form necessitates the knowledge of quite a goodly number of dermatoses which they resemble. Those which are ushered in as a generalized eruption will naturally make the diagnostician consider the possibility of one of the acute contagious exanthems, but fortunately there are distinguishing points from which one may arrive at a proper diagnosis. Common to all forms is the suddenness of outbreak and in the generalized forms the violence of development, both local and systemic; the brevity of the acute stage, and the relative quickness of defervescence. In the chronic conglomerated, fungating and exulcerating forms occupying at times almost the entire lower extremity, the risk of a faulty diagnosis is imminent, and sometimes fraught with grave danger to the patient.

In the oft-cited case¹⁸ of Köbner, amputation of the leg was avoided only in the nick of time and in his case of a scarlatiniform quinin eruption a prioress was quarantined for suspected scarlet fever for weeks. In Caspari's case,¹⁹ an alleged pemphigus chronicus turned out to be a bullous antipyrin rash. Innumerable other instances of this kind could be cited.

The pathology of bromin eruption is that of a more or less deep inflammation and will vary with the particular form it assumes. Changes in the papillary layer, in the periglandular tissues and the vessels surrounding them, a hyperkeratosis and parakeratosis and minute abscess formation in the corium are its main characteristics. Guttman²⁰ was the first to demonstrate bromin in the pustule and Fox and Gibbes²¹ found

Fig. 3.—Inside aspect of right leg showing the same centrifugal extension as Figure 2. Note smooth atrophic scaly appearance.

that the process starts in the cutis vera in the form of minute abscesses. The coil-glands show changes, but the pilosebaceous glands are slightly and only secondarily involved. Hence they declare that the so-called bromid acne is not a real acne.

While Von Wyss and Ulrich²² consider local intolerance of the skin as the cause of bromid acne, Laudenhimer²³ declares it to be a real symptom of bromin intoxication. According to Gley²⁴ and Cannizarro²⁵

bromin has a vicarious action on the ganglia almost similar to the active principle of the thyroid gland. Its administration may cause hyperthyroidism.

REPORT OF CASE

History.—A. L., aged 24, of healthy parentage, both parents living, had measles when 1 year old. At the age of 8, she contracted scarlet fever, complicated with kidney trouble and convulsions. After recovery she remained quite well for a year, when the convulsions returned. From this time on she was subject to epileptic fits, against which the use of bromids was advised. One year after the use of the drug—potassium bromid—she had acne of the face and on the border line of the scalp, and soon the right leg became the seat of a papulovesicular eruption. In the beginning discrete, later these lesions through conglomeration became confluent, occupying the middle of the tibial region, and calf of the right leg. Considerable pain and impairment of locomotion was present. One of the peculiarities of the case consists in the strange phenomenon that the eruption becomes aggravated in the fall and winter, and assumes a milder aspect or complete

Fig. 4.—Bromoderma, showing partial obliteration of the papillary paps. Spongiosis and intracellular edema. Dilation of lymph-spaces, moderate cell infiltration.

cessation in the spring. The patient denies a more abundant use of the bromid during the winter months, asserting that, in order to avoid seizures, she uses the drug more frequently during the summer. She had no attacks for seven years. When she stopped taking bromid the attacks returned. The eruption, however, continued when medication was interrupted. For six years she has taken a patent medicine containing bromid and for the last two months she has stopped medication entirely with the result at present of the complete cessation of active skin lesions. When I first saw the patient three years ago, she had on her left leg a patch of aggregated papulopustules, on an infiltrated base about the size of her palm and covered with crusts. On the left upper thigh a fungating ulcer the size of a half-dollar was observable, which developed through the exulceration of several confluent lesions. It was very painful and bled at the slightest touch. This latter symptom will be dwelt on presently. The most interesting change occurred on the right lower limb. Here an inflamed surface presented itself, extending from the upper third of the leg down to both malleoli. The front aspect (Fig. 1) shows a crusty, slightly-scalloped border studded with a few partly healed shallow ulcerations. The lower border ends abruptly in a semicircular concave line at about the crest of the tibia. The part which now presents a smooth

atrophic surface covered with thin cigarette-paper-like easily detachable scales, in the active stage showed an oozing, angry-looking surface, studded with innumerable pin-head- to split-pea-sized discrete and coalescing papulopustules considerably raised above the surface. The border of these papillomatous lesions had a honeycomb or sieve-like appearance from which a smegma-like offensive-smelling substance could be expressed. Some of these anthracoid and necrobiotic ulcerations as a remnant of former activity can yet be seen on the inner and outer border of the leg (Figs. 2 and 3). A most prominent feature, to my knowledge observed only once, though I have searched for it in the literature for the past thirty years, consists in a venous capillary hemorrhage from these ulcerations. At times, usually in the defervescing stage, a lamellous epidermic exfoliation would take place, exposing painful surfaces. Kudisch's case²⁶ resembles mine. It occupied three-quarters of the leg, had a vegetating appearance, bled easily, and had festooned borders. The hemorrhage, however, was not so abundant and there was no such epidermic exfoliation. My patient is not afflicted with hemophilia, has a normal blood-count, no nosebleed, no excessive menstruation and has healthy gums. At first varicose veins were thought of as the cause of this unusual symptom, but they were not found. Microscopic examination of an excised portion, however, revealed very marked dilatation of the blood- and lymph-vessels causing these extensive capillary hemorrhages in the pars papillaris. This finding explained the unusual feature of the lesion, caused by an excessive development of the vascular loops of the papillae, which formed the anatomic basis of the fungating lesion.

Histologic Examination.—By Dr. W. McMurtry of the Pathological Division of the Dermatological Department of the Vanderbilt Clinic.

Epidermis: This shows considerable acanthosis. The interpapillary prolongations are shortened or absent generally. The rete malpighii is slightly edematous in spots and the intercellular spaces contain more than the usual number of leukocytes. In one area only, marked parakeratosis is seen, but elsewhere the stratum granulosum and corneum are approximately normal; the latter shows hyperkeratosis in certain areas although clinically a marked tendency to scaling was seen. Certain rete cells show intracellular edema while others are somewhat swollen and stain faintly.

Derma: The entire derma is markedly thickened. The hyperplasia is due partly to a swelling of the collagen, an increase in the connective-tissue cells, fixed and transitional, and to a very marked dilatation of both blood and lymph-vessels and the presence around both of fairly dense cell infiltrations. The latter consists of some mononuclear and polynuclear leukocytes, a great many lymphocytes and a considerable number of plasma cells. Extensive capillary hemorrhages are noted in the pars papillaris. The walls of the larger blood-vessels show no evidences of degenerative changes. The elastic fibers are seen only in the deeper portion of the derma and appear thickened and broken. In the center of the sections there is an abscess. This has evidently begun as a follicular pustule and has then extended downward in an hour-glass shape. Surrounding it is a perifollicular infiltration of leukocytes, lymphocytes and connective cells with considerable number of red blood-corpuses. No giant cells and no chorioplaques were found. The sweat and sebaceous glands show periglandular infiltration. No evidence of either syphilis or tuberculosis is seen. Macrophage cells (*Schaumzellen*) as described by Passini²⁷ were not found.

Figures 2 and 3 show the convex outline of the lower border of the lesions and the centrifugal extension of the process downward. It has not extended beyond this limit in the last two years, but shows some activity, as seen on the upper border. The photograph was taken in February and represents the usual, although at this time slight, winter exacerbation.

tion. At present, in June, there are no ulcerations visible. The leg shows now a reddish-brown, smooth, slightly scaly, atrophic appearance. Its circumference is two inches less than the right one. The skin is tensely drawn and when pinched shows thin-ridged sallow papery folds. The whole process has lasted over three years. Bromids are taken and discontinued occasionally and for a short time. Bacterial cultures were negative, chemical analysis of sections also negative. The urine showed specific gravity of 1.013, traces of albumin, a large excess of indican, subnormal excretion of urea, frequent crystals of calcium oxalate. No bromids were detected after careful search. This finding corresponds with the veracity of the patient with reference to the ingestion of bromids.

DIFFERENTIAL DIAGNOSIS

In the foregoing the confounding of medicinal eruptions with syphilis has been dwelt on as the most serious of possible mistakes. I will try to offer some points on differential diagnosis. The sudden onset and the usual topographic distribution of these eruptions should be constantly kept in mind. Thus, a pustular bromid acne will develop more acutely than a pustular syphilid. It will show a predilection for the head, face, and extremities, while the syphilitic eruption will be found irregularly scattered over the body though it adheres more or less to a symmetrical arrangement. Bromid acne extends down into the cutis and is harder to the touch than the syphilitic or necrotic variety. The absence of inflammation in acne cachecticorum will serve to distinguish it from bromid acne; and from acne vulgaris it can be differentiated by its rapid and simultaneous appearance on the scalp and other hairy parts, by the absence of seborrhea oleosa and comedones and of other concomitant signs of pilosebaceous gland alterations. Finally, bromid eruptions like to develop on scar tissue.

Acne caused by iodine has a more acute onset. Ehrman,²⁸ however, classes it also with the bromid variety, while Szadeck attributes to the former a more acute beginning. I venture to remark that the affection of the mucous membranes as an almost always present symptom of iodine intoxication, will serve as an useful differential diagnostic sign. It should also be remembered that the iodine eruption shows a tendency to assume a bullous type.

To distinguish it from an exulcerated iododerma is at times very difficult. This develops from the bullous type, rarely observed in bromoderma and is accompanied by a highly inflamed, often erysipelatous, swelling, deeper necrobiosis and more intensive systemic disturbance. Moreover, it does not occupy, as does the bromoderma, the lower extremities by predilection, and does not show the marginal honeycombed smegma-excreting walls. The examination of the urine and anamnesic data will also prove helpful toward a correct diagnosis.

Both the bromoderma and the iododerma offer at times insurmountable difficulties to differentiation from the exulcerated gummous syphilid. Both form ulcers by central breaking down; both show steep walls. The studded pustular points around the margin, the flabby, sluggish feel to the touch of the bromoderma, will vividly contrast with the gyrate serpiginous configuration and convex margin of the ulcerating tuberculosyphiloderm. The Wassermann reaction and, eventually, a provocative salvarsan injection will soon solve the question.

TREATMENT

The antagonism between the two haloids, bromine and chlorine, one replacing the other and vice versa, has been utilized against bromine intoxication. Bromine retention in the system is due to ineffective kidney excretion. Bromine is absorbed quickly from the intestine, and if not excreted soon by the intestinal tract it rapidly manifests itself in the blood, displacing its chlorides. It is, therefore, administered in cases of bromine intoxication in epileptics when untoward symptoms require cessation of the bromids. The same holds good in skin eruptions. Theoretically, the application of saline compresses on bromodermas and the ingestion of table-salt would recommend themselves. Ulrich²⁹ recommends also salt baths for the same reason. Ointments invariably aggravate the condition. In my case rest and a 4 per cent. boric acid solution applied continually and held in place by a soft gauze bandage kept moist, was very effective.

Fig. 5.—Bromoderma. Pustulation, atrophy of epidermis. Hemorrhage and round-cell infiltration.

CONCLUSIONS

1. Drug eruptions may simulate almost any known skin affection.
2. A skin eruption starting suddenly without any prodromal symptoms is almost sure to be a medicinal eruption.
3. The violence of development, the preponderance of the local over the systemic disturbances is characteristic of drug eruptions.
4. The brevity of the acute stage and the quickness of defervescence constitute a notable asset in diagnosis.
5. The usual four stages of the acute contagious exanthems, namely, the prodromal stage, the eruptive, the fully developed and retrogressive and the desquamative stage are wanting.
6. The temperature never rises to the point shown by the acute exanthems and the affection of the mucous membrane is never so severe.

ABSTRACT OF DISCUSSION

DR. ERNEST L. McEWEN, Chicago: Cases of bromoderma are sometimes found in epileptics in which the skin eruption closely simulates blastomycosis. I recently saw a bromoderma in a girl of 16, an epileptic, who for a long time had been taking large doses of bromids. The lesion in this case appeared suddenly and extended rapidly, totally unlike what we see in true blastomycosis. Dr. Oliver S. Ormsby of Chicago, reported a similar case some years ago, in which the lesion spread with astonishing rapidity and closely simulated blastomycosis.

DR. A. RAVOGLI, Cincinnati: Not long ago I saw a child with massive tumors on the face and head. The child had been treated with the Roentgen rays and was getting worse and the treatment had also set up a Roentgen dermatitis. On inquiry, it was learned that the child had been taking bromids, and when this was discontinued, the lesions healed under simple treatment. I have also seen an acneiform eruption on the legs, due to bromid which was very difficult to diagnose.

DR. M. L. RAVITCH, Louisville: I do not agree with Dr. Weiss that these cases are so very unusual; I think many cases of bromodermas have been reported in the literature, and I have seen many cases more in private practice than in the asylums. The insane patients stand bromids better than normal people. I recall one case of bromoderma in an infant in which the diagnosis of small-pox was made and the child sent to an isolation hospital. I do not think bromoderma is confined to any particular season of the year. I have seen cases of bromoderma simulating blastomycosis, in winter, fall and summer.

DR. GEORGE M. MACKEE, New York: I had the opportunity of studying this case very carefully, and it offered considerable difficulty in the diagnosis. Among other things, we considered tuberculosis, syphilis and blastomycosis, and finally arrived at the correct diagnosis by the process of elimination.

DR. LUDWIG WEISS, New York: Bromoderma is not a very rare condition, but in my case there were some unusual features. The hemorrhages from the vegetations were at times very profuse, owing to the dilated venous loops in the papillary layer. I mentioned the seasonal occurrence of bromoderma only as a curiosity. We find that erythema-nodosum and other forms of erythema are worse in cold weather and improve in the summer. As Dr. MacKee has already pointed out, the lesions in this case had to be and were differentiated from a syphilid, pemphigus and other forms of eruption.

The side or base of the nail, however, may occasionally be first involved. Rarely the whole nail appears to be simultaneously attacked, and there is a more or less universal involvement of the whole horny substance. If the nail does not flake and break away, leaving a rough, uneven, diseased surface, it is very

Fig. 1.—Ringworm of nails.

much thickened and deformed. Only one nail may be involved, or several or all. The thumb, index-finger and middle fingers are the ones most commonly attacked, and as the nails are generally infected from

Fig. 2.—Favus of the nails.

FAVUS AND RINGWORM OF THE NAILS

MILTON H. FOSTER, A.M., M.D.
Surgeon, U. S. Public Health Service

NEW YORK

Favus and ringworm of the nails are supposed to be rather rare conditions. The finding of 101 such cases among the aliens arriving at Ellis Island during the first eight months of the present fiscal year goes to show that these disorders are probably more common, at least among our foreign population, than is generally believed.

Clinically both diseases present practically the same symptoms. The affected nail is thickened, brittle and sometimes even caseous. The natural color and transparency of the involved portion is lost and it becomes opaque and yellow or dirty-white in appearance. The process generally starts at the distal end and slowly infiltrates the nail toward the base, the diseased portion crumbling away gradually, because of the trauma to which the part is necessarily exposed in the ordinary vocations of life (Figs. 1, 2, 3, 4 and 5).

scratching the scalp, this distribution would be expected.

The disease does not appear to be painful nor does it seem, at least in our experience, to predispose toward setting up any acute inflammatory conditions of the surrounding soft parts.

PROGNOSIS

The process is essentially chronic, and if untreated continues indefinitely. The youngest patient whom we have encountered was 3 years old, the oldest 72. Reliable histories were hard to obtain, but one unfortunate asserted that this condition had been present for fifty-two years.

DIAGNOSIS

While the mottled, yellow, thickened and crumbly condition of the nails affected is highly characteristic, there are other conditions, besides an infiltration of

Fig. 3.—Ringworm of the nails enlarged, showing peculiar deformity.

Fig. 4.—Favus showing crumbling of the nails. This case was of four years' duration.

Fig. 5.—Ringworm of nails showing general yellow infiltration but no loss of substance.

these specific fungi, which resemble it very closely. These are syphilis, psoriasis, eczema, simple atrophy and hypertrophy, grave constitutional disorders, and some other skin diseases (Figs. 6, 7, 8, 9 and 10).

When the nails are affected by some general constitutional process, it is usual to find all of them involved. In ringworm and favus one or more often escape. Hypertrophic and atrophic conditions of the nails likewise involve all of them and the entire nail substance.

Fortunately it is not necessary to endeavor to find clinical points of difference, as a microscopic examination enables us to make the diagnosis with certainty.

METHOD OF EXAMINATION

Several drops of a 20 per cent. solution of potassium hydroxid in water are placed on a slide and a few fine scrapings from the suspected areas dropped in the solution. The slide is moderately heated once or twice and allowed to stand a few minutes. In a little time the suspected material becomes increased in size and soft in consistency. The "clearing-up" process may be hastened by gently separating and dividing the specimen with an ordinary teasing-needle. Several of the smaller bits of the softened scrapings are then placed on another slide and a drop of the

Fig. 6.—Simple hypertrophy of nails, end view, natural size. The patient, an alien, asserted that the condition had existed from birth.

Fig. 7.—Simple atrophy of nails, asserted to exist from birth.

Fig. 8.—Atrophic condition of nails due to severe burn received during childhood.

solution of potassium hydroxid added and a cover-slip placed over all. The slip is gently pressed down so as to make a fairly thin preparation.

Examined with a 4 eye-piece and a 7 objective with subdued light, the fungi appear as highly refractive, slightly greenish, transparent, branching threads among the partly disintegrated elements of the nail. If properly applied the potassium hydroxid solution clears up and partially dissolves the normal nail material, leaving the fungi standing out distinctly in the field (Figs. 11, 12, 13 and 14).

If the clearing-up process is too slow, reheating will hasten it. A little search may be

necessary to find them, but in many specimens every field will be found to contain a number of the threads. Generally the organism of both favus and ringworm when obtained from the nails appears as plain, hyaline, branching threads which here and there show faintly the separation into spores or which contain at more or less regular intervals a small, round, highly refractive spore. Occasionally, as in the illustrations, the spore formation is very prominent; but such a distinct separation into spores is not the rule.

INVOLVEMENT OF THE SKIN OF THE PALMS AND FINGERS

In a number of these cases I have noted that the skin of the palm and palmar surface of the fingers was unusually hard, horny, calloused, and had a tendency to crack and peel off in flakes. While this condition is generally observed to a moderate degree in laborers

Fig. 9.—Syphilis of the nails. The palm of this case is shown in Figure 17.

who use the pick and shovel constantly as a means of livelihood, yet it is unusual to see it to the extent present in many of these nail cases. We have lately been examining scrapings from these hands and have found the organism to be generally present in the skin, presenting practically the same appearance as in the nails.

While ringworm and favus of course frequently attack the glabrous skin, the clinical symptoms when involving the thickened horny epiderm of the palm and fingers is so different that there is no similarity to ringworm elsewhere (Figs. 15, 16 and 17).

The lesions are not red or circular, but merely what would ordinarily be considered as an extreme degree of callosity with a marked tendency to peeling, and it would appear that this disease in this location has been frequently overlooked, as I have found no description of this condition in the literature on the subject to which I have access.

DIAGNOSIS OF FAVUS FROM RINGWORM

As stated above, both disorders present clinically practically the same symptoms, and the fungi of ringworm and favus when obtained from the nails resemble each other so closely when examined microscopi-

Fig. 10.—Idiopathic loss and destruction of two nails. Case was kept under observation for a number of weeks and repeated examinations made, but no cause for the condition could be discovered.

cally that a separation of the two diseases on these findings alone is generally impracticable. If there be favus of the scalp or elsewhere on the body, or if the scalp bear the scars of old favus, it is proper to assume that the condition of the nails is also due to the same organism. Similarly if other parts are involved with ringworm, it is likely that this is also the cause of the onychomycosis. If neither active favus nor ringworm is present elsewhere, and there is

Fig. 11.—Photomicrograph of the organism of ringworm, X 330. It is unusual to see such marked spore formation.

no evidence of old favus, it is customary to make a diagnosis of ringworm, as ringworm of the scalp often disappears spontaneously after puberty and leaves no scars, and it is likely that the disease was transferred to the nails when it was active in the scalp.

COMPARATIVE FREQUENCY OF THE TWO DISEASES

In our series of 101 cases eighty-four were ringworm and seventeen favus. This would indicate that ringworm is encountered about five times as often as

Fig. 12.—Photomicrograph of the organism of ringworm, $\times 330$. It is unusual to see such marked spore formation.

Fig. 13.—Photomicrograph of the organism of favus, $\times 330$. Usually the spores are not so distinct. From the case shown in Figure 4.

favus. It may also be interesting to know that these 101 cases were discovered among 521,366 aliens who were examined. Roughly speaking, the ratio of cases was about one to five thousand of these foreigners.

TREATMENT

All authorities agree that the onychomycoses are extremely stubborn and resistive to all forms of treatment, and from the pathology of the disorder we would expect this to be the case.

The organism grows into the nail substance and down into the matrix, where it cannot be reached by any local applications. Any form of treatment must

Fig. 14.—Photomicrograph of the organism of favus, $\times 330$. Usually the spores are not so distinct. From the case shown in Figure 4.

be preceded by curetting and scraping away the diseased part of the nail so as to apply the antiseptic to the denuded surface. Continuous application of the desired remedy may be obtained by pulling rubber fin-

Fig. 15.—Ringworm of the palm. The nails also were involved.

ger-cots over the infected fingers and placing the medicine inside of them. Care must be taken to avoid setting up a general inflammation of the part by too severe or too prolonged treatment.

Stelwagon recommends dipping the finger-ends in a solution of mercuric chlorid, from 1 to 3 grains to

the ounce, for from five to ten minutes daily, allowing it to dry in and then enveloping the parts with an ointment of white precipitate or calomel, a dram to the ounce. He also recommends the use of a 20 per cent. solution of sodium thiosulphate, subsequently followed

years by several skilful men, one of them an eminent New York specialist. They were then treated as outpatients in another hospital for six months. At the expiration of this two years and six months' treatment, a microscopic examination showed the organism in all of them and they were apparently no nearer a cure after all this prolonged medication than at the beginning.

Fig. 16.—Favus of the palm; the nails also were involved.

by enveloping the fingers with an ointment of precipitated sulphur, 1 dram to the ounce. He also speaks of Harrison's treatment, which consists in applying a 6 per cent. solution of potassium iodid in equal parts of 20 per cent. solution of potassium hydroxid and spirits of wine for three or four minutes at a time. This is done two or three times at intervals of two or three days, and then Solution 2 is applied. This solution consists of 4 grains of mercuric chlorid dissolved in 4 drams each of spirits of wine and water. It is asserted that by this process mercuric

Fig. 17.—Syphilis of the palm, which clinically resembles favus.

iodid is formed deep in the tissues. Tincture of iodine and a host of other germicides have been recommended.

My experience with these remedies on the nails is too limited to justify my expressing an opinion concerning their utility. Concerning ringworm of the scalp, I am in a position to say that all medical applications in my hands have been extremely disappointing. We have the records of a family of three children aged, respectively, 6, 8 and 11 years, who were treated most persistently in two hospitals for two

Fig. 18.—Wiry hair and scarred scalp following favus in a young adult.

I am of the opinion that some of the reported rapid cures of ringworm of the scalp were either errors of diagnosis in the first place or that the cure could not have been sustained by a competent microscopic examination. I have frequently seen patients in whom the clinical symptoms promptly disappeared

Fig. 19.—Old favus of the scalp and active favus of the nails. Cause and effect.

in a few months on the application of the ordinary remedies, but in whom a microscopic examination revealed plenty of hairs infested with the spores of ringworm.

Much more encouraging reports are made from the use of the Roentgen ray, but as it has no direct action on the organism and acts simply by producing epilation (*Sequeira*), it would not appear to be applicable in combating the condition in the nails.

In view of the tediousness and uncertainty of medical treatment, the avulsion of the nail and the application of some germicide to the matrix may be justifiable. We have adopted this procedure in two cases.

PROPHYLAXIS

When the hands and nails are involved by either of these fungi, the likelihood of their transmission to others is probably much greater than in cases of the same disorder occurring in the scalp. The sufferer is constantly scattering far and wide particles of disintegrated nail substance and flakes of skin which are loaded with the organism. His hands are continually in contact with objects of common use and very often directly with the persons of others. More ideal conditions for disseminating the infection could scarcely be devised. Imagine the situation should a barber or hair-dresser contract the disease in the nails and continue to practice his vocation!

Fig. 20.—Old favus, recovered, of the scalp, in man aged 28. Note the loss of hair and the coarse, wiry appearance of the hair present.

Favus of the scalp or nails is a severe and loathsome disease. Unless energetically and carefully treated from the start for a very long period, it always results in permanent loss of the hair and scarring of the scalp in the areas involved with great disfigurement (Figs. 19 and 20).

Fortunately the disease is rather infrequent in America and our strict immigration inspection prevents new cases from being introduced from those foreign countries in which it is prevalent.

In view of the danger to the community at large, it would seem that favus should be added to the list of notifiable diseases and that cases occurring in this country should be placed under such restraint by the local health authorities as may be necessary to prevent the spread of the disease to others.

My thanks are due to Surgeon L. L. Williams of the U. S. Public Health Service for his kindness in permitting me to refer to these cases. I desire also to make my acknowledgments to Assistant Surgeon J. H. Smith, who has done the microscopic work, and to Pharmacist Charles Slough who has given valuable assistance in making the negatives.

Ellis Island.

A COURSE IN SURGICAL TECHNIC*

WILLIAM COGSWELL CLARKE, M.D.

AND

FREDERIC W. BANCROFT, M.D.

NEW YORK

The course in surgical technic here described was designed to meet a demand in the surgical training given in Columbia University. It is realized that familiarity, by actual observations on animals, with the use of aseptic materials, the appearance and manipulation of living tissues, the control of hemorrhage, and the methods employed to prevent contamination and subsequent infection of recent wounds, is an equal advantage to the graduate whether he enters practice immediately on graduation or prepares himself further by a hospital training. The opportunity to participate in operating-room routine, such as the preparation of the patient, the surgeon, the instruments and materials, is now of recognized value, and this recognition has created a need for special training in the details of aseptic surgical technic.

The course is given to fourth-year medical students in the Laboratory of Surgical Research, where there is a well-equipped animal hospital. In order to provide an opportunity to educate recent hospital graduates in teaching methods as well as to instruct the students, the teaching staff has been made unusually large. It includes twelve instructors in surgical technic and two in surgical pathology, all of whom have had surgical service in a hospital.

Four of these instructors are on duty at the same time. Each instructor serves for three months, but, by a scheme of rotation, he acts as assistant instructor during the first two, supervising the students at one table where he fills the place of second assistant, while during the third month he is instructor in chief and attending surgeon at the University Animal Hospital, where he makes a daily visit. The schedule is so arranged that each instructor becomes the chief twice in a period of twenty-four scholastic months.

The course is an optional one, but so great is the interest it has aroused that at least three-fourths of the fourth-year students elect it, and each of the sections into which the class is divided contains ten men on an average. Each section receives instruction for eight periods of two hours each. It is divided into groups of three men, so that an average section furnishes operating staffs for three tables, and the men at each table rotate at successive lessons in the position of anesthetist, first assistant and operator.

The nurse in charge is a graduate of a hospital training-school. She is familiar with all surgical requirements and has supervision over the animal hospital and operating-room, under the direction of the attending surgeon on duty. At its initial lesson she instructs each section in the preparation of surgical supplies and their sterilization, the care of instruments and utensils, and in the manipulation of sterile gowns, gloves, etc. She also prepares for the operative sessions exactly as in the operating pavilion of any first-class hospital.

The operating-room is furnished and equipped on modern lines. It is 20 feet square, lighted by side-lights and skylights, and provided with powerful arc-lights. Adjacent rooms are used for sterilizing, anes-

* From the Department of Surgery, College of Physicians and Surgeons of Columbia University, New York.

thetia and private operations, and there is a detached room for necropsies. The sterilizing plant includes an autoclave, instrument boiler, utensil boiler and water sterilizers of the latest type.

The animal hospital has been fitted up with every regard for the animals' comfort. Each animal has a separate cage, and there are especially heated ones for recovery from anesthesia. The entire time and attention of one man is given to these animal patients. The animals themselves, as well as their surroundings, are kept scrupulously clean with the aid of a bath-tub, sluicing-hose, proper disinfectants and abundant light and ventilation. As the hospital is maintained to treat animals with surgical lesions, many dogs suffering from tumors, infections and prolapsus uteri have been received as private patients. Thus the students under direction of the attending surgeon have had the opportunity of assisting at operations on real pathologic conditions. In his daily visits the attending surgeon inspects all the animals and gives such directions for

performed, and intestinal suture illustrated. Technic of applying dressings.

THIRD SESSION: Lateral entero-enterostomy.

FOURTH SESSION: Posterior gastro-enterostomy.

FIFTH SESSION: End-to-end entero-enterostomy, by suture.

SIXTH SESSION: Exploratory laparotomy, for a stab-wound of the abdomen, inflicted under anesthesia. The location and repair of the lesions are demonstrated.

SEVENTH SESSION: Nephrectomy, illustrating the treatment of the pedicle.

EIGHTH SESSION: Repetition by each table of any operation which has been unsuccessful.

The routine of a session is as follows: The chief instructor outlines briefly, at the beginning of the lesson, the steps of the operation to be performed, illustrating them by diagrams on the blackboard. He then assigns the students to their duties, and the usual routine of an operating-room begins. The anesthetist starts the anesthesia in the etherizing-room, the animal is placed on the operating-table and the field prepared by the first assistant (the hair has been removed and the animal given a full bath on the day before by the attendant). The skin is prepared by scrubbing with green soap and water, then with alcohol 70 per cent., and rinsing with mercuric chlorid 1:10,000. The table is then wheeled into the operating-room and draped with sterile sheets by the operator, who has previously scrubbed up and has put on cap, mask, gown and gloves, under the supervision of his instructor.

During the operation the instructor at each table directs every step and calls particular attention to the observation of asepsis, handling of instruments, placing of sutures, control of hemorrhage and the importance of handling living tissues with gentleness. Before leaving the room the student operator writes a description of his procedure on the history sheet of the chart, which is to hang by the animal's cage.

At the conclusion of the operation, every step of which has been

done under full anesthesia in every case, suitable dressings are applied to the wound and the animal is carried to the hospital and placed in a "warming cage," in order that chill may be prevented and the animal made comfortable. The animal receives special attention during convalescence, its temperature and general condition are noted daily on the chart, and the diet is carefully regulated by the attending surgeon. The student-operator is urged to visit his convalescent patient and to consider the outcome of his procedure of importance equal to that of the operative result on a human being.

At the beginning of each operative session, necropsies are performed by one of the instructors in surgical pathology on any animals which have died as a result of operation. A few, selected from the convalescents, are chloroformed and necropsied for the purpose of showing the students the contrast between the normal repair at various intervals after operation, and

Operating-room for the class in surgical technic, Department of Surgery, Columbia University.

their care as may be necessary to the nurse in charge and her assistant. Daily notes of temperature and general condition are entered on each patient's chart for the information of the surgeon and the students.

In order to preserve uniformity of instruction, the professor of surgery has prescribed a definite series of demonstrations and operations for the course. A printed outline of these is furnished to every student at his first lesson.

FIRST SESSION: The course opens with a lecture and demonstration on (a) suture materials and instruments; (b) preparation and sterilization of surgical supplies; (c) the administration of anesthetics to animals; (d) the preparation of the animal for operation; (e) the sterilization of the surgeon's hands, and relative values of different methods in use, and (f) prescribed method of putting on cap, mask, gown and gloves.

SECOND SESSION: The abdominal incision and its repair in layers. Repair of wounds in the intestine. Enterotomy

the pathologic conditions produced when an operation has been unsuccessful. Attention is drawn to the resistance of the healing wound to tension, in both abdominal and intestinal walls, to the constant formation of peritoneal adhesions, and to the benefit or harm which may result from the attachment of the great omentum to the various viscera. Preceding a necropsy on a pathologic animal, the student who operated on it is questioned as to his procedure, and as to any postoperative symptoms which might indicate the cause of death. He is also questioned regarding the treatment he would pursue with a human patient who exhibited similar signs and symptoms, and is asked to give his reasons therefor. Thus a constant effort is made to keep clear in the minds of the students the clinical aspects of the case, and the importance of necropsies is emphasized, as a means of correlating them with the various pathologic conditions and processes that are found to exist. This practice is intended as an aid to the interpretation of physical signs and to the understanding of the principles of treatment in human surgery.

Specimens of tissues are selected at the necropsies, and microscopic sections are made to show the students the cellular morphology of all common postoperative conditions, including wounds healing by first intention, infected wounds, and the various types of peritonitis, with or without adhesions. At the close of each necropsy, the student-operator is required to write a complete report of the pathologic findings, and these reports are bound with the histories. To increase the interest of the students, a comparative record of the results of each section's work is kept, which proves a stimulus to both students and instructors.

The routine performance of necropsies has brought out many interesting surgical facts which should be of lasting benefit to the students. Peritonitis occurred most frequently after the operation of end-to-end intestinal anastomosis. In the cases of gastro-enterostomy the most frequent cause of death was pneumonia, suggesting the increased percentage of pneumonia due to surgical interference in the upper abdominal cavity. To indicate the value of pathologic material that may occur during the year and the benefits that may be derived from the study of such material, a few of the unusual causes of death occurring with the various operations are briefly mentioned here:

1. *Gastro-Enterostomy*.—One case of enormously distended stomach with contracted intestines, due to a small band with a valve-like action, causing obstruction to the entrance to the jejunum. One case of death due to inanition caused by anastomosis of the stomach to the descending colon; here sufficient care had not been taken to identify the loop of intestine used for the anastomosis.

2. *Enterorrhaphy*.—One case of gangrene of the intestine in which the intestinal clamps had been too tightly applied.

3. *End-to-End Entero-Enterostomy*.—One case of cirrhosis of the liver with ascites; death was due to oozing. One case of infection of the abdominal wound, followed by protrusion of the omentum with beginning gangrene.

4. *Exploratory Laparotomy for Stab-Wound*.—One case of general peritonitis, due to an overlooked stab-wound in the intestine. One case of thrombosis of the

superior mesenteric vein, with gangrene of the small intestine. This was probably due to excessive traction on the mesentery, as no other cause could be found. One case of general peritonitis due to a gauze sponge that had been left in the abdominal cavity.

The sections that saw these last three necropsies learned a lesson in surgery which they will probably never forget, so clearly was brought out the necessity for careful handling of the tissues, and for keen systematic observation.

Intussusception was found to be a frequent cause of death, and has apparently no relation to the type of operation performed. It is probably due to the handling of the intestine. Both cross-sections and longitudinal sections have been made to show the students the relations of the layers of intestine and constriction of the mesentery in such conditions.

The private animal patients admitted to the hospital have been the means of demonstrating several neoplasms as well as other instructive conditions. One student section had the opportunity of operating on congenital oblique inguinal hernia occurring in three youthful pigs, all from the same litter. The students had the subsequent satisfaction of having these three animals returned home, discharged cured, and the wounds healed by first intention.

The advantages of a course of this kind are numerous. The existence of a staff of instructors, each occupying in turn the position of chief, not only makes each instructor's service short enough to maintain constant enthusiasm, but also acts as a stimulus, because of the element of competition. Each surgeon has an opportunity to observe the teaching methods of his associates, and to note their merits or defects, with a view to increasing his own efficiency. The combination in a single course of the technic of operative procedure with the pathologic findings in the cases in which operation has been performed leads the student, when brought into contact with clinical cases, to reason in terms of pathologic processes and conditions. This assists him to correlate his knowledge of anatomy, pathology, bacteriology and physiology with surgery. He is trained to base his conclusions on observations of facts rather than on dogmas.

Finally, after such a course the student has become acquainted with the technic of asepsis, the use of surgical instruments and the other essentials of general surgical procedure; he has learned that an operation must be conducted exactly and methodically, and he has felt a personal responsibility for its success or failure.

When, therefore, he enters practice and is confronted with the necessity of operating, he is no longer an untried apprentice. Already familiar with the fundamental principles of aseptic surgical work, he is enabled to avoid many a costly mistake, and is far better fitted to do credit to himself and justice to his human patients.

437 West Fifty-Ninth Street—43 West Fifty-Fourth Street.

The Logical Starting-Point.—The diseases common to child life are spread by the mingling of the sick with those who are well. The public schools are the places where the children of all ages and degree assemble. It follows then that the public school is the logical point at which to begin the important work of controlling those diseases that are spread as has been stated, by the mingling of the sick with the well.—*Bull. Chicago School Sanit. Instr.*

THE MEDICAL SCHOOL AND THE STATE*

H. S. PRITCHETT, PH.D.

President, Carnegie Foundation for Advancement of Teaching
NEW YORK

The layman who ventures to speak concerning a matter so technical in some respects as medical education owes perhaps an explanation to the public and to the medical practitioners. What can the layman say as to the training of medical experts which is of value or which the public cares to hear?

There are three main reasons why the layman has a right to be heard in the matter. First of all, medical education is primarily a matter of education, not a matter of medicine. The educational test which shall be imposed, the premedical education itself, the educational methods of the medical school, are all matters not of medicine but of education.

Secondly, the layman who gives thought to these matters has a right to speak from the point of view of his own interest for it is the layman after all who is to be either made or marred by the medical practitioner. The general public is profoundly interested in the question whether the medical expert has been rightly trained for his profession.

In the third place, the layman is necessarily interested in the medical school as a matter of state administration. The legal conditions which are finally to be imposed on medical education may originate with medical practitioners, but they will be passed on and finally put in form by legislators. The matter of the public health will be in the keeping of skilled physicians, but the form of administration under which they will work and the relations of the different parts of this organization will be decided by laymen.

To put the whole matter tersely, the practice of medicine is a quasi public profession. The laws which admit to its practice must be framed by those who are not members of the profession, but who are looking at it from the point of view of the public good. Medicine will never gain its rightful place until the intelligent laymen, the legislator, the citizen, realize the public nature of the profession of medicine and their own obligations as to its support, its standards and its regulation.

It is this last relationship, namely, the relation of the state to medicine and to medical teaching, which we need at this time most clearly to develop. We need to distinguish between the opportunity of the individual on the one side and the obligation of the state on the other.

The public health of the inhabitants of a state is without doubt the largest single interest with which a state needs to concern itself. Expressed even in commercial terms it exceeds all others. Disease, ill-health, insanitary public conditions, cost more than any other form of public neglect. The conservation of the public health is therefore the largest interest to which the state must give its attention.

Our American commonwealths have begun only within a very few years to be conscious of this problem. In a few states steps have been taken to deal with the problem in orderly and efficient form. It therefore seems worth while on such an occasion as this to lay special emphasis on this public duty; to call attention to the fact that the medical school and the hospital ought to form the very heart of those

agencies by which the state undertakes to deal with the public health and that there must be worked out a form of administration under which the state shall coordinate all its agencies, the board of health, the medical school, the hospital, the laboratory, for an efficient handling of the problem of the public health.

The present demand for an effective organization of public health agencies arises out of the progress of what we call to-day scientific medicine as compared with what twenty-five years ago was empirical or sectarian medicine.

Following the great discoveries of the chemists, the biologists, the bacteriologists, all sectarian divisions of medicine became meaningless. Men came to realize that medicine is applied science and that it should rest like all other technical and scientific practice on the results of experimental knowledge. It avails itself of whatsoever could be shown by careful experiment to be true in the practice of any medical body. It subjects every appliance to the scientific test, and while this process wiped out all distinctions of caste it set up as a condition for entering the profession the possession of the inquiring, active, critical, scientific spirit. Sects in medicine are no more possible under this conception than in botany or astronomy. Deliberately to label oneself an allopath or a homeopath or an eclectic is to return to a past epoch of medical history.

One of the first results of this change of attitude in the profession in its relation to laymen lay in the willingness of the practitioner to admit the limitations of his knowledge. The student of scientific medicine no longer hesitates to say he does not know; he does not pretend to universal knowledge; but he has possession of methods which ultimately will lead to the solution of most if not all of our problems. Scientific medicine does not pretend to say that the solution of all these has now been attained.

Another significant result of the introduction of the scientific method and its universal activities lies in the fact that the emphasis on preventive medicine becomes greater. Modern medicine realizes that it is not enough to cure those already ill; it is not enough to build hospitals for the sick; it is not enough for the surgeon to relieve the pain of those actually suffering. All this is a part of the work of modern medicine, but a still greater part lies in the prevention of illness, in creating conditions favorable for health, in so dealing with the problem of the public health that there shall be a minimum of disease, a minimum of ill health, a minimum of suffering. It is the rise of preventive medicine, based on the science of chemistry, biology and physics, which has brought home to the state the realization of its own supreme duty in safeguarding the physical well-being of all its people. The state has long accepted the problem of caring for the helpless sick. To-day it faces the duty of preventing the helpless from falling into unnecessary illness.

The working out of this problem means not only the betterment of sanitary conditions, not simply the provision against infection and the stamping out of nuisances, but it means more than all else the education of the whole people of a state to the knowledge of the elementary sanitation laws. This education of the people lies at the very base of preventive medicine, and preventive medicine lies at the base of the state's ability to safeguard the public health.

The rise of preventive medicine and the enlargement of the state's function in the conservation of the public health is rapidly bringing about a change of attitude in our whole social and economic treatment

* Address delivered at the dedication of the Robert W. Long Hospital of Indiana University at Indianapolis, June 15, 1914.

of disease and ill health. In the past the care of the sick poor has been a matter of charity; the obligations of society no less than the ideals of Christian service have urged civilized men to continual effort for those suffering from illness who are in want of the necessities of life. This obligation and this service will not cease, but the vista which preventive medicine opens up enables us to anticipate a time when a large share of the suffering and disease which now falls to the lot of the poor will be prevented when the conditions of living will be more wholesome, when the need of charitable service will be limited to those cases which no preventive measures can safeguard. The entrance of the state into the great work of health preservation, while it will not be a substitute for private philanthropy, will nevertheless relieve much of the suffering to which private philanthropy has hitherto ministered, and it ought to diminish in an ever-increasing measure the suffering and the misery of poor and rich alike. This is one field of human endeavor in which an ounce of prevention is worth many pounds of cure.

If one looks forward a decade into the future along the lines which modern scientific medicine opens up, and if he admits that the state must shoulder the responsibility for a uniform and effective system of public health administration, it is clear that the state can accomplish this enormous service, that it can conserve the great interest of the public health effectively, only by some harmonious coordination of its various agencies. To-day the problem of the public health is dealt with by a number of agencies, often-times unrelated and disassociated. On the part of the state itself stands an official board of health with similar boards representing communities and cities. The medical school, the hospital and the laboratory are the natural agencies through which any administrative board of health must carry out its measures. Finally, the practitioners themselves must stand in some relation to the state's health activities. Some method must be worked out by which the profession of medicine, quasipublic as it is, shall find a relationship to the state and to the state's work in the matter of the public health which shall be more definite and more satisfactory both to the public and to practitioners than the present arrangement. To state the matter a little more definitely, if the state is to enter on a constructive program in the matter of the public health, if the general public through the state is to reap the benefits of a wise system of preventive medicine, an organization capable of dealing with the problem must be devised, and that organization must be elastic enough to include the board of health, the medical school, the hospital, the laboratory and the practitioner.

What form of organization will suffice for this fundamental public work? That question is the practical one which is to-day being attempted by many American states.

To accomplish the end sought there is needed not so much a hard-and-fast organization as intelligent cooperation between those which have been created. Thus a state board or commission with its executive officers will doubtless continue to be the organization through which the state authority will be exerted. The medical school with its hospital and laboratory will continue to be under the control of the university. Experience has shown that whatever be the weakness of the university, it has been the only agency through

which the spirit of scientific inquiry and devotion has flourished. Only in a university have scientific ideals had their fair chance to get into the practice.

What is needed, therefore, is the closest correlation between the state board of health and the university school of medicine. In the state of Indiana it is fortunate that all these agencies are under state control. This simplifies enormously the problem of working out a right coordination. However important and far-reaching are the powers of a state board of public health, the medical school will always remain the heart of the public health activities for the reason that in the medical school practitioner and student meet. The enthusiasm of the teacher and of the investigator give a spirit to the public health effort which no other combination can give. Here as nowhere else the laboratory of the chemist and of the biologist and of the pathologist are brought face to face with the problems of disease in the hospital. Of all human efforts, of all human organizations as yet devised, no other has brought together the same qualities of skill, of devotion, of enthusiasm, as that which comes from the association of student and teacher, of experimenter and practitioner. The medical school with its teachers, its students, its laboratories, its hospital, will be both the inspiration and the hands of the public health service. Fortunate it is for this state that it already controls and is developing a modern school of medicine, imbued with the spirit of scientific medicine, in touch with the research spirit of the day, and ready to develop into the most fruitful agency for the solution of the problems of the public health which this commonwealth must face. It is because I regard the medical school, and when I speak of the medical school I mean to include faculty and students, laboratories and hospital, it is because I regard the medical school and its proper development, its cooperation with the board of health, as the greatest step in the public health service that I venture to spend the remaining few minutes of my talk in a consideration of certain conditions which from the point of view of the educator make for the right growth of the medical school and therefore of the state service.

If the medical school is to be the right hand of the board of health, it must not only cooperate by the training of medical students, by the use of its laboratories for tests and examinations and by the study of disease in its hospital, but it must also take the broadest possible conception of its duties in the matter of education.

There are two fields of medical education which are generally overlooked and which the state school of medicine must vigorously undertake—one is the education of the public in the elementary knowledge of sanitary matters, the other is the education of the present generation of practitioners into an appreciation of the modern conception of the profession of medicine. I venture to spend a few words on each of these topics.

The education of the public into a practical knowledge of the elements of the science necessary for the conservation of the public health is still in its infancy. It has not yet been successfully undertaken by any school of medicine for its own state. By lectures, through the daily press (which has always been a cordial ally in such an endeavor) in all the ways by which a democracy can be educated, the people of a state must be taught the elementary science which prevents disease, cuts down the death-rate of infants, prevents the spread of infection, brings the appreciation of fresh

air and cleanliness to every citizen. Only in a very limited degree does the average intelligent man appreciate how much of the disease and suffering in his community is due to his own neglect. Finally, such a campaign of education must do something to teach the average citizen to use ordinary care in the selection of a medical adviser. It must teach him to discriminate between the graduate of a commercial medical factory and the graduate of a school whose ideals represent the highest step in our civilization, for there is no ideal of human service more creditable to our progress in civilization than that which is set before the student of medicine in our better schools.

There remains still an unfulfilled duty to the men now in the practice. Ill-trained and unfit as many of them are, they represent in a large majority of cases the victims of a condition. Few men deliberately choose a defective and impossible medical training. Well-meaning young men by the thousand have gone into such schools in the honest belief that they were to receive a fitting preparation for the profession of medicine. The victim of the commercial medical school usually finds out his mistake after he gets into practice. If he has the right spirit he seeks by every possible means to repair his defects. To such men the state school of medicine should offer a most hospitable opportunity.

The postgraduate school of medicine as it has hitherto been conducted has generally grown up apart from the university medical school. It has been generally conducted by groups of practitioners—sometimes with excellent purposes and motives, sometimes with a very strong commercial flavor. The postgraduate school should be by all means a part of the university medical school. To no other men will the spirit and ideals of the university hospital, laboratory and medical school be more welcome. And in no way can the medical school educate the people of a whole state so surely as to establish a helpful relation with every practitioner in the most remote village who has ambition for improvement. Every such postgraduate student becomes a center of education in the public health.

It ought to be clear to the layman as well as to the practitioner of medicine that a single school of modern medicine in a state like Indiana is the true solution of the problem of educating practitioners of medicine and of serving the public health. Indiana to-day has about as many doctors to the square mile as any state in the Union. For every 500 inhabitants, including men, women and children, there is an Indiana physician. This result is in part due to the fact that near the state of Indiana is the city of Chicago, which is the great factory for medical degrees. I regret that an institution in this state still conducts a medical school in Chicago. There is no justification for a second school of medicine in Indiana. One moderate-sized medical school, conducted on right lines, can supply more physicians than the state of Indiana can possibly absorb. For many years to come there will continue to be many more physicians, at least in name, than the state needs. In time we may hope that with a growing education of the public, the layman will select his practitioner of medicine with at least as much care as he would select a clerk or a foreman, that he will at least make some inquiry as to the source of his medical education and the extent of his medical experience. Until the public can be educated to know the difference between a well-trained practi-

tioner of medicine and one who obtained a degree by short-cut methods, the whole problem of the public health will be delayed.

In this connection I venture to spend a moment to emphasize one phase of this problem which is very commonly misunderstood. The plea put forward in behalf of the commercial medical school is couched in terms calculated to deceive the public. The commercial medical school describes itself as an institution maintained in the interest of the poor boy, and, secondly, as an institution devoted to the training of the country physician. If one reads the catalogs of these institutions, one can easily believe that in the commercial medical school as in no other institution the interests of the poor boy and of the resident of the country are deeply cherished. Both claims are without foundation. The poor boy pays as much money to go to a commercial medical school as he does to a medical school conducted in the highest spirit. This has to be because the commercial medical school exists only on the fees which the students pay, notwithstanding the fact that those who conduct such schools expect their return in the by-products of the school rather than in the fees. The boy of limited means is too often tempted into such a school and discovers too late that the kind of education he receives is not that which enables him to deal with disease.

The argument of the commercial school that only by its existence can the country side be settled with physicians is clearly misleading. The very idea is abhorrent to all sense of social justice. Are we deliberately to create a situation in which the men and women who live in the country are to accept an inferior type of medical practitioner? Is our civilization so constituted that we must provide one class of practitioners for the city and another for the country? As a matter of fact there is absolutely nothing in this contention. It is true that the graduates of the strong medical schools and of the weak medical schools alike go in overwhelming numbers into the cities. It is equally true that the graduate of the good medical school goes to the little town and to the country wherever he can make a living. A most careful examination has shown that a physician of the best training can be secured in any village or country-side where the practitioner of medicine can earn even a modest living. If there were being turned out from the medical schools only men rightly trained in some proportion to the number of places available, one can foresee the time when all places which could furnish a moderate living to the physician could be supplied. There are parts of our country so sparsely settled that no practitioner of medicine, whether well-prepared or ill-prepared, could make a living. For such a situation, a solution of a different kind must be found, and this is one of the problems with which the public health service of the state will in the long run deal. The fear that the country would be bereft of doctors if the inferior medical schools were abandoned is one of the singular theories, founded partly on lack of knowledge of the situation, partly on the assertions of those directly interested in keeping alive such schools.

One has only to recall the way in which young men come into the practice of medicine to realize the hollowness of the statement. The country or village doctor is in nearly all cases the neighborhood boy—often times the son or the nephew of the resident practitioner. He gets his preliminary education in the neigh-

borhood and goes off to the medical school and returns to take up the practice gradually being given up by his elders. The question whether he goes to a poor school or a good one has little to do with his return.

I venture also to say one word of the significance to the state and to the public health service of an educated profession of medicine. No method has been devised in our country or on the other side by which unfit men can be excluded from the profession of law, of medicine, or of the ministry, or of any other great profession, but the experience of the older country shows that there is one condition which can be imposed which does more than all others to bar out the unfit and the unworthy, and that is the standard which is imposed by the demand for a high order of preliminary education. No other condition can be imposed which will in the long run bring together so unselfish, so skilled, so devoted a class of men into a profession as the demand for a good preliminary education. Among our American communities this demand also has been looked on as somewhat undemocratic, an argument which has been used with the greatest possible effect by the commercial medical school. As a matter of fact, there is nothing undemocratic in such a demand. The right to practice medicine is not one into which a man is born. It is a right conferred on him by the state under such conditions as the state may fix. There is no condition which the state can make which in the long run will bring into the service of the profession and of the public, physicians of such high order as the requirement that they shall be, first of all, educated men, and the influence which the profession itself will have on the public will never attain its right proportions until such a condition has been accepted.

Looking forward then to the history of medicine in your commonwealth for the next decade, one can well believe that the conservation of the public health will be one of the chief functions of the state, that this work will be carried out by an organization so planned that all its factors may cooperate freely and heartily, and that the very center of such organization, furnishing to it the life-blood of devotion, of enthusiasm and of high endeavor, will be the state school of medicine, where practitioner and teacher, where student and investigator mingle together in an atmosphere which is charged not only with scientific skill, but also with the highest conceptions of patriotism.

Safe Drinking-Water.—Allen J. McLaughlin in *Public Health Reports*, June 26, 1914, says that there is a tendency in America to accept any raw water, however bad, as a source of supply for a municipal filtration-plant. This places an unreasonable burden on the filtration-plant, which not only depends on proper mechanism, but which also must be operated under careful bacteriologic control and is subject to the results of human error. While properly constructed filter-plants can produce safe water from bad raw water, especially by the use of hypochlorite or liquid chlorin, the responsibility of effecting such purification every hour of every day in the year is unreasonable and unfair, and raw water demanding such extraordinary treatment, constitutes a constant threat of disaster. There is no margin of safety under such conditions, and raw water should be furnished of such character that a plant can turn out safe water without the aid of chemical germicides. This would reserve chlorination as an additional margin of safety for use in extraordinary fluctuations of the raw water or during accidents to the plant.

INSTRUCTION IN ROENTGENOLOGY

ADOLPH HENRIQUES, M.D.

Radiologist in Charge, Presbyterian Hospital and Eye, Ear, Nose, and Throat Hospital; Visiting Radiologist, Charity Hospital; Assistant in Physiology, and Instructor in Clinical Medicine and Radiology, Tulane University of Louisiana, Medical Department

AND

LODILLA AMBROSE, Ph.M.

NEW ORLEANS

The committee of the Deutsche Röntgen-Gesellschaft has submitted its report on instruction in medical roentgenology in the German higher institutions, this report has been sent to the medical faculties of the German-speaking higher institutions of Germany, Austria and Switzerland, and it has also been published.¹ Some parts of it have been taken from data collected by Klingmüller, Kienböck, Holzknicht and Kreuzfuchs, and published in Volume XIX of the *Fortschritte*.

After calling attention to the rapid advances made in Roentgen science during a decade and a half, and to the utilization of this science by nearly all other branches of medicine, the report says:

Therefore, if complete medical training is to be secured in the universities, it is quite essential that there be the possibility of obtaining a systematic knowledge of roentgenology.

It is from this point of view that the Deutsche Röntgen-Gesellschaft has undertaken to direct the attention of the medical faculties of the various German-speaking institutions to the necessity of thorough instruction in roentgenology, and to the desirability of having the fostering cooperation of the universities in future research in this field.

The report summarizes the results of the "unwearied work of doctors and physicists" in the few years in which the x-rays, that is, the unknown rays, have been subjected to investigation. This work has made roentgenology an "independent specialty," which has both manysidedness and also oneness. Just as the fact that no physician can dispense with a knowledge of internal medicine does not exclude the need of specialization in internal medicine, so the utility of some insight into Roentgen procedures on the part of the general practitioner does not nullify the advantages of specialization in roentgenology. This specialty requires in a marked degree a broad and deep foundation in general medicine and the other specialties. Even in these few years, the Roentgen technic has become complicated and hence difficult, whether used for diagnostic or therapeutic purposes. Some of the injuries that a false therapeutic technic may cause have already been found out. To have any real value, both the fluoroscopic examination and the making of plates must be carried out with accurate technic, and the interpretation must be made with good knowledge of the sources of possible errors. Faulty, or even moderate, Roentgen technic is ineffective, and may be injurious.

To quote a few sentences from this report:

The erroneous idea that one needs only to be well versed in general medicine, in order to be able to interpret a Roentgen picture, is even to-day too wide-spread. Only on the basis of a many-sided experience gained by earnest study continued for years is it possible to analyze correctly that which is seen, and then, to interpret it, and to separate the essential from the non-essential. The interpretation of the

1. Der Unterricht in der medizinischen Röntgenologie auf den Deutschen Hochschulen, *Fortschr. a. d. Geb. d. Röntgenstrahl.*, Hamburg, 1913, xxi, 245.

Roentgen picture, therefore, requires knowledge which embraces almost the entire field of medicine and a good part of physics, and in addition a fundamental special experience. This is demonstrated also by the frequently observed fact, that many a specialist in another branch, who was using roentgenology in his specialty, finally either devoted himself entirely to roentgenology, or, if he remained true to his own subject, was no longer able to follow the advances of roentgenology. To master simultaneously and completely roentgenology and another specialty is in general impossible. The field of roentgenology has already become too great for that.

It was in view of such facts as these that the Deutsche Röntgen-Gesellschaft (with 609 members, almost nine-tenths of whom are active roentgenologic physicians) at its eighth congress, 1912, unanimously adopted the following resolutions:

1. Roentgenology is a fully justified medical specialty.
2. The roentgenologist is a specialist, and as such, and in accordance with generally accepted usages, is consulted by physicians or patients for the making or the verification of a diagnosis.
3. The roentgenologist, in addition to general clinical methods, makes use of the Roentgen procedure. He decides which procedure (photograph, fluoroscopic examination, orthodiagraphy, teleroentgenography, etc.) should be used.

This consensus of opinion has led to the expression of a desire that "in accordance with the ever-increasing importance of roentgenology this specialty henceforth be taught in the higher institutions by its own representatives, by a lecturer with this as his main line who receives a teaching appointment for this specialty."

The details of the report on the existing instruction in roentgenology in the German-speaking higher institutions might not be pertinent at this distance. But the conclusion drawn from these data is that this instruction is not now adequate, that roentgenology is not being taught to an extent consonant with its importance. At present almost the only available way for a physician to orient himself in the general field of roentgenology is to itinerate from one factory to another for certain phases of the subject, and from one clinic to another for others. The fact is emphasized that this situation does not accrue to the interest of this specialty or to that of medical science as a whole. The entire subject in all its multiplying ramifications should be transferred to the universities, and teaching should be done by specially prepared instructors. The retention of Roentgen outfits already in use in connection with the several specialties is contemplated, but in correlation and cooperation with the central roentgenologic department. The anticipated resultant advantages to all are great. Medical roentgenology will be taught where all other branches of medicine are taught—in the universities. Each of the other specialties need teach only such parts of roentgenology as pertain directly to its work. The Roentgen specialists themselves "constantly can test out the newly created methods of the restlessly advancing technic, before the clinics squander time and money on them; further, in difficult cases they can assist the physicians of the other clinics technically and scientifically; they can support the proficient with expert advice, and, above all, enlarge the scientific work of the specialty, as well as prepare a secure place for roentgenology in academic instruction."

The report also notes that, if it is granted "that every physician entering practice must have at his dis-

posal a certain but not too limited degree of systematic information about roentgenology," then "there follows also the necessity of taking account of this requirement in state medical examinations."

The positions taken regarding instruction in roentgenology by these compatriots of Roentgen seem justified by the facts presented. This being granted, these positions may be considered as applicable as fully to this country as to the countries for which they were originally formulated.

This report has led us to a study of the roentgenologic instruction in the United States. For this purpose has been chosen the list of the "A plus" group of medical colleges as given in THE JOURNAL of the American Medical Association, August 23, 1913, p. 585. The latest catalog (that is, the publication representing the teaching work of 1912-1913 or the announcements for 1913-1914) of each of these institutions has been carefully examined for information regarding instruction in roentgenology of whatever quality or quantity. Only a summary of the details of this compilation will be given here:

1. *Titles Used in Designating This Instruction.*—The terms used in referring to the subject are, actinography, radiography, radiology, roentgenology, Roentgen ray and x-ray, with more institutions using the word "roentgenology," than any other one term. This is also the word adopted in Germany. Of the institutions whose catalogs furnish any data, two have professors of this one subject, two have an associate professor for this and another specialty combined, two have an instructor for roentgenology; two, a lecturer; one, a demonstrator, and some of these have assistants in addition; five recognize positions of varying titles in connection with some hospital: all of which tends to show that up to the present time there has been no standardizing of the position of the teacher of roentgenology in American medical colleges.

2. *Roentgenology as a Distinct Department of Instruction.*—Four institutions—Northwestern University, Harvard University, Cornell University and the University and Bellevue Hospital Medical College—recognize roentgenology as a distinct department of instruction coordinate with the other medical specialties. In those institutions in which a course in roentgenology is offered but in a subordinate relation to some previously existing department, there is no uniformity as to the department with which it is incorporated.

3. *Year in Which Instruction in Roentgenology is Offered.*—Concerning the institutions whose catalogs furnish any data, the facts are: undergraduate course, required, in second year, 1; in third year, 2; in fourth year, 6; in third and fourth years, 1; undergraduate course, elective, in fourth year, 1; graduate course, 1.

4. *Number of Hours of Undergraduate Instruction in Roentgenology, and Character of Instruction Whether Didactic or Laboratory* (exclusive of use of plates to illustrate work in other subjects).—Concerning the institutions whose catalogs furnish any data, the facts are: *Didactic*, instruction given but hours not stated, 4; "all day throughout the year," 1; 9 hours, 1; 11 hours, 1; 16 hours, 2; 17 hours, 1; 30 hours, 1;—*laboratory*, "elective," 1; instruction given but hours not stated, 1; 40 hours, 1; 51 hours, 1.

The self-evident conclusion from this study of the official catalogs of the medical colleges in the "A plus" group is that in about one-third of them instruction in roentgenology is omitted altogether, and that in the

others it has no standardized status. Further, this being the case in the highest group, it is fair to infer that still less instruction in this subject is given in the other groups. Therefore, it becomes apparent that the opportunities in this country for the systematic study of medical roentgenology are very meager.

Yet the Council on Medical Education of the American Medical Association enumerates "Roentgen-ray apparatus" among the "essentials of an acceptable medical college," and the Association of American Medical Colleges in its "proposed minimum standard for clinical equipment," says, "Adequate rooms and equipment must be provided for x-ray work and for electrotherapeutics." Highly complicated technical apparatus certainly implies technical instruction in its use, its limitations and its dangers.

As a branch of medicine, roentgenology is in touch with all other branches of medicine. Although it is associated more closely with some of them than with others, experience has demonstrated its possible service to the other medical specialties, and the growing dependence of these specialties on roentgenologic findings. Roentgenology is a new science but it has already made contributions of value. In view of the extensive and increasing applicability of the Roentgen rays both in diagnosis and therapy, has the time not fully come when some adjustment should be made in American medical colleges which will give to roentgenology its logical place in medical instruction and research? If it is not taught systematically, how can the best results be obtained in actual practice? Can any American medical college otherwise well-equipped afford to ignore it? Does roentgenology not deserve a definite status in the medical curriculum?

PUBLIC HEALTH WORK AS A CAREER*

JOHN A. FERRELL, M.D.

Assistant Director-General, International Health Commission

WASHINGTON, D. C.

The medical profession has always made a strong appeal to young men of fine character, as offering a career unsurpassed in opportunities for real human service. It is essentially that type of profession. To-day, with the rapid development of the science of preventive medicine, the opportunities are still greater, and the appeal to young men of high aims stronger than ever before. Particularly is this true in the comparatively new field of public health service.

This is the day of the efficiency expert. The public health officer is an efficiency engineer in the most important department of human life—good health. He is a constructive searcher after truth. Instead of tamping and patching up the machinery here and there, he builds anew. He has to know the whole works, not merely one process; he deals with society as a whole, instead of with a few separate units. Translated into the terms of his calling, his task is to keep all the people well and strong, instead of concerning himself only with the unfortunates who come to him in dire necessity. Economically, he is a wholesaler, free and unrestricted in his operations, dealing in a commodity everybody wants, rather than a retailer with whom, generally speaking, nobody really wishes to do business. He is the servant of the community, tied to no

man, but free to do his duty as he sees it, whether that duty be to purge a Cuba of yellow fever, clean a pestilential Panama, or wipe out the double scourge of hookworm and typhoid from some rural community. The public health officer is dependent for his material rewards, not on haphazard personal fees, but on the good faith of a public which is fast learning to pay adequately for adequate service by experts.

For a young man on the threshold of his career, however, there are certain very practical points to be considered. At least three questions may be asked by any vocation, whether it be public health work, private medical practice or any other. First, what are the immediate chances of employment? Second, what is the compensation? Third, is the work sufficiently permanent in character to warrant giving one's life to it? These three questions are fundamental. How does the field of public health work measure up to them, especially when compared with that of private practice of medicine?

It may be stated with full assurance at the outset that there are already more positions open for trained health officers than can be satisfactorily filled. The demand is increasing all the time. It comes from federal, state and city health departments; from the International Health Commission and similar quasi-public health agencies; from the schools, and more recently from rural counties. Medical inspection of schools has made rapid strides in the last year or two, both city and county. Twenty-one states now have medical inspection laws, ten of which are mandatory; while in many of those states without special laws on the subject many individual cities have inaugurated medical inspection systems. The medical inspection work is more and more being centered about the whole-time health officer. Maryland is looking for men to fill positions created by the sanitary district bill passed at the last legislature. New York State is in the market for a large number of trained health officers. North Carolina employs eleven whole-time county health officers at salaries that attract capable men irrespective of residence. Sooner or later all the states will exert that control over hygienic and sanitary conditions which a few now exert, and this will mean an ever-increasing demand for public health officers to give their entire time to the community. Already some of our educational institutions are coming forward with special courses to train men for the new work—the "School for Health Officers" of Harvard and Massachusetts Institute of Technology is sufficiently well known; and at least five American universities—Harvard, Pennsylvania, Michigan, Wisconsin and Tulane—now grant the degree of Doctor of Public Health for special public health work over and above the requirements for the regular medical degree.

With the increased demand for trained health officers has come higher compensation for such work. Specially trained men are commanding salaries much more nearly adequate than in the past. In the days of political appointments the candidate for health officer was glad to get a small regular salary for a little of his time to supplement his always uncertain and frequently uncollectable private fees. With whole-time men engaged, better salaries come as a natural development. Already the salaries paid health officers compare more than favorably with the present incomes of private practice. Investigation has shown that, despite the large earnings of a few medical men, the average

* Address delivered at the Commencement Exercises of the Medical College of Virginia, Richmond, June 2, 1914.

salary for a physician in the United States is between \$800 and \$1,200.¹ In New York City the salaries of health officers range from \$900 to \$1,500, but this amount is felt to be so little that the physicians are allowed to take some outside practice. Salaries of school medical inspectors in twelve cities enumerated by Dr. Heitmuller, of Washington, D. C., ranged from \$1,200 to \$2,000.² These figures do not include the administrative pay in public health work, which is of course much higher. Surgeon-General Blue, of the United States Public Health Service, notes that the municipalities are offering such good inducements that many of the men in his branch of the government are leaving the service to take positions as health officers, and he foresees a steady rise in compensation.

That salaries will continue to grow better in public health work is evident from an analogous development in another field in which what was once a private, individual matter has become a public function—that of education. When school superintendents were elective the pay was low and tenure insecure, and few thoroughly capable men were attracted to the profession. To-day the city school superintendent is one of the highest paid of municipal officers, and enjoys an independence of political affiliations that is the envy of other public officials. It happens that in the case of state and county school superintendents the process has not been completed; in some states partisanship has been entirely eliminated from the schools, and school officers are on a thoroughly professional basis; in others this is not yet the case. It is possible to look over the states and tell at a glance where the pay is high or low, according to whether the position is or is not political. New Jersey's commissioner of education is an educational expert who receives \$10,000 a year. His politics have never been inquired into; he was brought from a distant state because he was considered the best man for the position. Nebraska's state superintendent of public instruction, nominally with the same qualifications as New Jersey's commissioner, is elected on a party ticket. He is paid \$2,000 a year. The county superintendents in the six to nine hundred dollar class are for the most part in states that have not yet fully accepted the scientific attitude toward expert public service; the \$3,000 county superintendents are in states that have learned, as all will soon learn, the basic economy involved in high pay for expert service.

What has taken place in the field of education is taking place just as definitely in the field of public health work. More enlightened public sentiment with regard to medical standards is removing the health officer from politics and increasing his pay to a point at which well-trained men are sought and obtained for the work.

To ask if public health work will be permanent is to ask whether good health will always be desired and whether community spirit will grow. The public health officer need not fear for employment; he is a necessary factor in progress. His field, dependent as it is on community good health, rather than individual ill health, will grow ever more important as prevention replaces treatment in the handling of disease. The young man inclined to choose between private practice and public health work would do well to bear in mind the essentially permanent character of community

health service, unaffected by the many temporary conditions that make or unmake opportunities in the field of private practice.

One thing is certain. The field of public health work is no place for the poorly trained medical man. Medical men are needed for health work, but only highly trained medical men. The public is going to employ more and more health officers; it will be liberal in its compensation, but it will insist on men specially equipped for the work. At present it is difficult to get the precise training that is needed. The universities and medical schools are just beginning to awake to the supreme importance of positive health work in the community as compared with mere negative combating of disease. The health officer should have something that will do for his future work what the hospital does for the ordinary medical man. In default of other agencies to provide this special preparation, new agencies will have to be devised; and pending this, promising young men who have completed the regular medical course in the institutions of higher grade should be selected to serve an apprenticeship under trained health officers in actual service, both in the field and in the administrative offices.

Once get the idea of the trained health officer at his work, mapping a community, surveying it with a view to sound principles of sanitation and inspiring the citizens with the ideals of healthful living, and it does not require a much greater flight of the imagination to see this work of survey, prevention and health-teaching done everywhere—in all local communities, under county supervision; in all counties, under efficient state supervision, and all states under efficient national supervision. One might go a step further and picture a broadly organized international health organization, making a survey of the leading nations, taking the best to be found in the experience of the different nations and setting up standards for all the nations to attain. All this may seem too far afield; or at least too remote for men now living; but it does not seem so impossible of realization when we consider the other scientific achievements of our day, in medicine itself, if you please; and a vision like this will in any case serve to reassure those who may enlist in this war that it is not a war of a day, or even of a generation, but a permanent indispensable service to society.

There appears to be some danger that the public health work may to some extent escape the control of those most competent to direct it—the medical profession. This is emphatically a movement in which leadership belongs to the trained medical man. The lay sanitarian, no matter how efficient he may be in his own particular line, cannot wholly take the place of the physician, with his peculiarly valuable background of education and human experience. As routine medical treatment yields before preventive medicine, readjustment will have to take place; but I believe that readjustment is nearer than many of us realize; and I have sufficient faith in the men of my profession to believe that in large measure this readjustment will come from within. Something like it is already taking place in England, where the community ideal has recently gone forward by leaps and bounds. The spirit certainly exists among medical men in the United States. Does not the constitution of the American Medical Association recite that its aim shall be the "enlightening and directing of public opinion in regard to the broad problems of hygiene"? And the corresponding section of the constitution of the North

1. *Pennsylvania Med. Jour.*, 1901-1902, v, 362.
2. From unpublished memoranda.

Carolina State Medical Society goes even further in acknowledgment of the public health aim of the medical profession—it not only urges the extension of medical knowledge, better standards of medical education and “the enlightenment and direction of public opinion in regard to the great problems of state medicine,” but urges as the motive for this “that the profession shall become more capable and honorable within itself, and more useful to the public in the prevention and cure of disease and in adding comfort to life.”

Surely no richer field of labor can be conceived of than that of public health work. The medical man has always stood for something a little more than just his profession; as confidant, as valued counselor in time of trouble, as the keeper of family secrets, he has played the rôle of an idealist in human history. Add to these individual and personal attributes of the old-time physician the ideals of the health officer in his social service of to-day, of positive effort in behalf of all his fellowmen, and you will produce a band of men who will indeed be valued guardians of the outposts of civilization.

THE VALUE OF THE MEDICAL COLLEGE LIBRARY TO THE STUDENT*

CHARLES FRANKENBERGER

Librarian, Jefferson Medical College

PHILADELPHIA

Only in recent years have medical colleges realized the value of a medical library as an essential part of the college equipment. Medical students two decades ago were without the help of a medical library; they had to be content with a case of books, largely obsolete, in a corner of some out of the way room. A student in those days was expected to do his reading in his preceptor's library. Often older graduates, on visiting our library, have said to me, “We didn't have anything like this when I was a student.”

A modern medical library, in charge of an experienced librarian, is one of the requirements of the Council on Medical Education of the American Medical Association. To receive recognition as an acceptable medical college, “The college should have a working medical library to include the more modern text and reference books with the ‘Index Medicus’ and thirty or more leading medical periodicals; the library room should be properly lighted and heated, and easily accessible to students during all or the greater part of the day; it should be equipped with suitable tables and chairs, and have a librarian in charge.”

The maintenance of a well-equipped medical library as a part of the medical school or college has a number of advantages. In the first place it is a convenience to the students in that it makes it unnecessary for them to carry about a number of their own text-books to which they might wish to refer. The library, however, is not intended to take the place of the students providing themselves with such books as they should have for their own use in their homes. Some students are not in a position to supply themselves with all the necessary text-books required, and for these the library provides an aid much desired and appreciated. Were it not for the library facilities, these students

would be compelled to follow such notes as they could take in the lecture room and clinic. The instruction so acquired would satisfy those students who were simply bent on gaining sufficient knowledge to pass their examinations. They would not, however, have the broader knowledge and culture obtained by the students who supplemented their lectures and clinics by reading the fuller accounts in the various standard text-books and systems, as it is not possible for any teacher to cover in detail in the time allotted the many subjects of his particular branch of medicine as fully as it is given in an authoritative text-book. It is necessary for the student, while in college, to confine himself to certain text-books and instruction of his teachers, but by reading he can become familiar with the opinions and methods of other authorities which it would be well for him to know, not so much for use during his medical course, but as a broader knowledge for use in his future professional career.

Another advantage of the medical college library and a comfortably equipped and attractive reading room, easily accessible, well-lighted and heated, is that it encourages the student to use the library during his odd moments instead of wasting his time on the streets or elsewhere.

Possibly the greatest advantage of such a library is that it places about the student an environment which has a tendency to inspire in him a desire to read and become acquainted with the literature of his profession so freely available. It gives the student the opportunity to keep in touch with the literature in the more important current medical periodicals, and to become acquainted with the recent books and monographs on special subjects. If there is only time to look hastily through them and to become sufficiently familiar with them to know that such a work has been written on that particular subject, it will be valuable knowledge that will prove helpful at some future time.

To cultivate in the student the habit of reading in the odd moments and spare time of his medical course is to be encouraged and fostered in every way, for the possession of such a habit after entering on practice will be of inestimable value to him. It is safe to say that many who do not acquire this habit during their college career never attain it after graduation.

The great difficulty in endeavoring to encourage the acquiring of this habit by the student is the very limited spare time allowed in our already crowded curriculums.

The teacher who is himself thoroughly familiar with the literature of his profession can accomplish a great deal in the way of creating in the student an interest in seeking further information and knowledge by referring in his lectures and clinics to the masterpieces of medical literature, or to the biographies of those to whom the medical profession is indebted for their pioneer work or achievements in medicine and surgery. He can refer his students to the originals of articles which present results of experiments or investigations that have proved epoch-making. This avoids the necessity of the student investigator using his limited time to wade through a lot of valueless and ephemeral literature in order to find these masterpieces of scientific research.

Dr. Thomas McCrae of our faculty has followed the plan of assigning to certain students the preparation of a brief biography of those on whose experiments and investigations have resulted the foundation

* Extract from a paper read at the seventeenth annual meeting of the Medical Library Association, Atlantic City, June 22, 1914.

principles of some of our progress in medicine. These biographies are read by the student before the class prior to the lecture on the particular disease or subject at hand, and are made more interesting by the additional remarks that may be made by the teacher.

It is a regrettable fact that the great majority of our medical students graduate and pass out of the medical college and enter on their professional careers with practically no knowledge of how to obtain the literature on a particular subject should they wish to prepare a paper or to do research work. They do not have the least idea where and how to look up references and that such references even exist outside of their text-books. They know practically nothing of the value and contents of the "Index Catalogue" and the "Index Medicus" or how to use them. Of course they have had little or no occasion to refer to these during their college course, but it seems to me that every graduate in medicine should be familiar with these publications and know how to use them.

Would it not be well for our medical colleges to provide somewhere throughout the course in medicine an opportunity for instruction in the use of the various indexes and bibliographic reference works so valuable to the medical writer and investigator? Could not this instruction best be given by the one most familiar with the subject, the librarian in each institution?

This instruction would include the explanation of the use of the card catalogue of the local library, the contents, arrangement, mode of using to obtain the information desired in the least space of time and in the most thorough manner, of the various bibliographic indexes such as the "Index Catalogue of the Library of the Surgeon-General's Office," the "Index Medicus," the various year-books, annuals, *Jahrbücher* and *Jahresbericht*; where and how to find abstracts, as in the "Current Medical Literature" section of *THE JOURNAL* of the American Medical Association and the *International Abstract of Surgery* and the various *Centralblätter*; and information as to how to obtain publications from the Library of the Surgeon-General's Office in towns where there are no medical libraries or where the library does not have the desired books. All this and much more helpful information might be given in such a talk.

While the student would not recognize the value of such instruction while in college he would readily appreciate it when entering on his medical literary work.

Would not the "knowing how" thus acquired by the student be an impetus to him in the preparation of any papers that he may wish to write or in doing reference work for others?

When a student has fully realized the value of a library, when he has learned the relative value of the literature of medicine and has become acquainted with the various methods of bibliographic work and the use of library facilities, he has laid a literary foundation that will be an efficient means in acquiring a better medical education and a broader medical culture.

It is hoped that the foregoing will impress on those in authority in our medical colleges the essential value of the medical library to the institution and especially to the students, and help to inculcate in the student a greater desire to avail himself of the abundant opportunities afforded for the widest possible knowledge to be acquired in his chosen profession.

Tenth and Walnut Streets.

FOREIGN BODIES IN THE BLADDER.

LOUIS GROSS, M.D., SAN FRANCISCO.

While the literature teems with interesting cases of foreign bodies in the bladder, the first case here recorded is unique in many respects and should teach us a few valuable facts.

C. K., of San Bernardino, Cal., hotel proprietor, was referred to me with the following history: Family history was negative. Patient had some difficulty in urination, for the relief of which a suprapubic prostatectomy was done, June 27, 1912. Following the operation the patient had two postoperative hemorrhages; suprapubic drainage was removed three weeks later; patient urinated through the urethra from five to six weeks after operation; bladder wound closed in the ninth or tenth week. Patient consulted Dr. George K. Herzog, June 16, 1913, almost one year later, and was immediately referred to me. His history was one of continued frequency of urination, nocturnally and diurnally, tenesmus, and stinging pain at glans penis. Urinary examination showed turbidity, acid reaction, 1.030, no casts, many red blood-cells, no crystals, and a few spherical epithelial cells. Cystoscopy showed a calculus in the bladder.

June 19, litholapaxy was done and a large amount of fragments was removed with the evacuator. Patient also passed a considerable number through the urethra. As not all were crushed in the one sitting, June 21, Nitze's operation-cystoscope with lithrotite attachment was used; as operation became too painful, nitrous oxid-oxygen anesthesia was given. Many small fragments were broken and then a foreign substance was caught in the jaws of the instrument, which was also attached to the bladder wall at the site of the previous prostatectomy. A suprapubic cystotomy was then performed and what was thought, when observed through the operation-cystoscope, to be a piece of gauze, proved to be a piece of the ordinary soft-rubber catheter about 20 F. and about 1½ inches long. The catheter was attached to the wall of the bladder at the site of the former operation. Patient made an uneventful recovery. July 16, cystoscopy showed a normal bladder. This case is recorded to warn us of the great danger lurking in the use of deteriorated rubber drainage-tubes, to urge the testing of all tubing before insertion into the bladder, the avoidance of tubing too small in caliber, and to examine all cases of this character cystoscopically as a control.

A physician called on me one morning much disturbed and related the following interesting story: A patient of his had a stricture of the urethra which could not be passed by sounds of ordinary size. After the use of all the smaller sizes of exploratory bougies he used a filiform, succeeded in entering and immediately passed a Gouley tunneled sound. During this manipulation the filiform suddenly slipped beyond his reach and entered the bladder. I informed him that a stricture admitting only a filiform would not allow the passage of an operation-cystoscope for its removal; furthermore if he would wait a few days the filiform would pass out. Being obdurate to this plan of procedure, the patient was brought to my office the same afternoon. Various sounds were tried without success until I changed my position from the right to the left side of the patient. This is a method we should take note of, as often the tip of the sound will be caught in a pocket and the shifting of one's position from left to right or vice versa will cause supposed strictures to disappear immediately.

With the Buerger operation-cystoscope and with a long pair of Buerger forceps passed through this instrument, the edge of the filiform was grasped and removed through the instrument. I may state here that in the removal of filiforms, it is necessary to grasp the filiform at either thin end and not in the thick center.

This case teaches us the necessity in the treatment of filiform strictures of exercising great care in grasping the filiform with a pair of hemostatic forceps as soon as the Gouley tunneled sound or catheter is passed over the filiform; otherwise it may be carried into the bladder.

45 Kearny Street.

MEDICAL COLLEGES OF THE UNITED STATES

657

ANNUAL PRESENTATION OF EDUCATIONAL DATA BY THE COUNCIL ON MEDICAL EDUCATION

Below are given brief descriptions of the medical colleges in the United States and Canada that are legally chartered to teach medicine, several of which do not grant degrees. The name, address, year of organization, history and date when first class graduated are given in each instance. Unless otherwise stated, a class graduated each subsequent year. Where official reports have been received from the college, information regarding faculty, entrance requirements, length of term, fees, students (excluding specials and postgraduates), graduates, name of dean and next session is given without discrimination, regardless as to whether the college is sectarian or not. In a few instances in which such reports were not received the information published is from other reliable sources. Figures for graduates include all who graduated since July 31, 1913. Extracts of rules and the membership of the Association of American Medical Colleges are shown following the list of colleges. Figures showing population of cities and states are taken from the United States Census Bureau's returns for 1910. Statements have been added showing the preliminary requirements held by state licensing boards where those requirements include one or two years of collegiate work.

ALABAMA

Alabama, population 2,138,093, has two medical colleges, the School of Medicine of the University of Alabama and the Birmingham Medical College, located, respectively, in Mobile and Birmingham. The population of Mobile is 51,521 and of Birmingham 132,685.

In order to secure licenses to practice medicine in Alabama, students matriculating in the session of 1915-16 and thereafter, must have completed *two years* of work in an approved college of liberal arts including courses in physics, chemistry, biology and a modern language prior to entering on the study of medicine.

Birmingham

BIRMINGHAM MEDICAL COLLEGE, Avenue F and Twentieth Street. Chartered in 1894. The first class graduated in 1895. In 1913 became the Graduate School of Medicine of the University of Alabama. There are 19 professors and 13 assistants, total 32. The course of undergraduate instruction now embraces one session of eight months. Only seniors will be enrolled. When this class has graduated, the college will cease to do undergraduate teaching. The fees are \$130. The secretary is Dr. E. P. Hogan. Registration, 1913-14, 57; graduates, 30. The twenty-fourth session begins Oct. 1, 1914, and ends May 28, 1915.

Mobile

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE, St. Anthony and Lawrence Streets. Organized in 1859 as the Medical College of Alabama. Classes were graduated in 1861 and in all subsequent years except 1862 to 1868, inclusive. It was reorganized as the Medical Department of the University of Alabama in 1897. All property was transferred to the present, one year and, for the session of 1915-16, *two years* of college work will be required for admission. The faculty consists of 14 professors and 41 lecturers and assistants, a total of 55. The course of study covers four years of thirty-two weeks each. The total fees for each of the four years, respectively, are \$160, \$155, \$155 and \$175. The Dean is Dr. Eugene D. Bonduant. The total registration for 1913-14 was 94; graduates, 21. The forty-ninth session begins Sept. 24, 1914, and ends June 9, 1915.

ARKANSAS

Arkansas, population 1,574,449, has one medical college, the Medical Department of the University of Arkansas, located in Little Rock, a city of 45,941.

To secure licenses to practice medicine in Arkansas, students matriculating in the session of 1915-16 and thereafter must have completed at least one year of collegiate work including college courses in physics, chemistry, biology and a modern language before beginning the study of medicine. This applies to all graduates of 1919 and thereafter.

UNIVERSITY OF ARKANSAS MEDICAL DEPARTMENT, Markham and Center Streets. Organized in 1879 as the Medical Department of Arkansas Industrial University. It assumed the present title in 1899. In 1911 the College of Physicians and Surgeons united with it and the new school was made an integral part of the University of Arkansas. The first class graduated in 1880. The faculty consists of 15 professors and 36 lecturers and assistants, total 51. Entrance requirements will be increased to include a year of collegiate work beginning with the session of 1915-16. The fees are \$125 for each of the first three years and \$150 for the fourth year. The Dean is Dr. Morgan Smith. Total registration, 1913-14 was 95; graduates, 34. The thirty-sixth session begins Sept. 14, 1914, and ends May 13, 1915.

CALIFORNIA

California, population 2,337,459, has eight medical colleges. Four are located in San Francisco, a city of 416,912 inhabitants. They are Leland Stanford Junior University School of Medicine, College of Medicine of the University of California, Hahnemann Medical College of the Pacific and the

College of Physicians and Surgeons. The College of Physicians and Surgeons and the California Eclectic Medical College are situated in Los Angeles, population 319,198. The Oakland College of Medicine and Surgery is in Oakland, population 150,174. The College of Medical Evangelists is located at Loma Linda, a village of 110 people.

To secure licenses to practice medicine in California under the "physician's and surgeon's" certificate, students matriculating in medical colleges in and after the session of 1915-16 prior to such matriculation must have completed at least one year of recognized collegiate work including college courses in physics, chemistry, biology and a modern language. This applies to all graduates of 1919 and thereafter.

Berkeley-Los Angeles-San Francisco

UNIVERSITY OF CALIFORNIA COLLEGE OF MEDICINE, University Campus, Berkeley. Second and Parnassus Avenues, San Francisco. Organized in 1863 as the Toland Medical College. The first class graduated in 1865. In 1872 it became the medical Department of the University of California. In 1909 the College of Medicine of the University of Southern California, at Los Angeles, by legislative enactment, became a graduate department. This Los Angeles portion was changed to a work of the last two years at San Francisco. The faculty is required for 21 professors and 55 associates and assistants, a total of 76. The course covers four years of nine months each. Fees for the four years respectively are \$195, \$180, \$165 and \$165. The Dean is Dr. Herbert C. Moffitt, San Francisco. Total registration for 1913-14 was 124; graduates 18. The forty-second session begins Aug. 7, 1914, and ends May 8, 1915.

Loma Linda

COLLEGE OF MEDICAL EVANGELISTS.—Organized in 1909. The faculty over five years of nine months each, but includes a study of the Bible and evangelistic training—non-medical subjects. The total fees each year are \$136; matriculation fee, \$5, payable but once; graduation fee, \$10. The Dean is Dr. Alfred Shryock. The total registration for 1913-14 was 75; graduates, 6. The sixth session begins Sept. 13, 1914, and ends June 8, 1915.

Los Angeles

COLLEGE OF PHYSICIANS AND SURGEONS, 516 East Washington Street. Organized in 1903, first class graduated in 1905; became Medical Department, University of Southern California Aug. 11, 1909. The course covers four years of nine months each. One year of collegiate work is required for admission. The faculty consists of 19 professors and 59 associate professors, lecturers and instructors, a total of 78. The fees for the four years respectively are \$177, \$172, \$160 and \$175. The Dean is Dr. Charles W. Bryson, Delta Building, Los Angeles. The registration for 1913-14 was 153; graduates 34. The next session begins Sept. 9, 1914, and ends June 10, 1915.

CALIFORNIA ECLECTIC MEDICAL COLLEGE, 846 Lyon Street. Organized in 1879 at Oakland as the California Medical College. Removed to San Francisco in 1887. Suspended in 1906. Reorganized at Los Angeles with the present title in 1907. Classes were graduated in 1880, and in all subsequent years except 1907. The registration for 1913-14 was 38; graduates, 11.

Oakland

OAKLAND COLLEGE OF MEDICINE AND SURGERY, Thirty-First and Grove Streets. Organized in 1900, opened in 1902. The first class graduated in 1906. The faculty numbers 44. The course covers four years of nine months each, and the classes are limited to ten students each. The total fees for each of the four years, respectively, are \$210, \$200, \$175 and \$175. The Registrar is Dr. Edward N. Ewer. The total registration for 1913-14 was 15; graduates, 3. The thirteenth session begins Aug. 18, 1914, and ends May 22, 1915.

San Francisco

HAHNEMANN MEDICAL COLLEGE OF THE PACIFIC, Homeopathic. Sacramento and Maple Streets. Organized in 1881 as the Hahnemann Medical College. The first class graduated in 1884. In 1888 it became the Hahnemann Hospital College of San Francisco. It assumed the present name in 1902. It has a faculty of 22 professors and 16 lecturers, instructors, etc., a total of 38. The course covers four years of thirty-four weeks each. Total fees for the first year are \$155, and \$100 for each of the other three. The Dean is Dr. James W. Ward.

391 Sutter Street. The total registration for 1913-14 was 40; graduates, 5. The thirty-third session begins Aug. 11, 1914, and ends April 29, 1915.

COLLEGE OF PHYSICIANS AND SURGEONS, 344 Fourteenth Street.—Organized in 1896. The first class graduated in 1897. The faculty numbers 24. The course covers four years of nine months each. The fees for each of the four years, respectively, are \$165, \$160, \$160 and \$185. The Dean is Dr. L. W. Spriggs. Registration for 1913-14 was 34; graduates, 8. The eighteenth session begins Sept. 2, 1914, and ends June 4, 1915.

San Francisco-Palo Alto

LELAND STANFORD JUNIOR UNIVERSITY, SCHOOL OF MEDICINE, University Campus, Palo Alto, and Sacramento and Webster Streets, San Francisco.—Organized in 1908 when, by an agreement, the interests of Cooper Medical College were taken over. The faculty consists of 36 professors and 57 lecturers, assistants, etc., a total of 93. Three years of collegiate work are required for admission. The course covers four years of nine months each. Students matriculating in September, 1914, and thereafter will be required to take a five year course including a year of practical or intern work prior to graduation. The total fees for the first are \$160; for the second, \$155 and for the third and fourth years, \$150 each. The Dean is Dr. R. L. Wilbur, San Francisco. The total registration for 1913-14 was 75; graduates, 13. The fifth session begins Sept. 2, 1914, and ends May 17, 1915.

COLORADO

Colorado, with a population of 799,024, has one medical college, the University of Colorado School of Medicine. The first two years of the course are given at Boulder, the seat of the university, while the last two, or clinical years, are given in Denver, which has a population of 213,381.

The Colorado State Board of Medical Examiners will register without further examination graduates of medical colleges in good standing who present licenses issued after examination granted by any other licensing board. The law permits any one, graduate or non-graduate, to try the Board's written examination. No graduate of 1914 or thereafter is eligible to obtain a license in Colorado on indorsement of his credentials unless he graduated from a medical college which at the time he matriculated required at least two years' study without conditions in an accredited college of liberal arts which work must have included courses in physics, chemistry, biology and one modern language.

Boulder-Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged Jan. 1, 1911, when the legal right to teach the last two or clinical years in Denver was secured. The faculty embraces 49 professors and 24 lecturers and assistants, a total of 73. The work embraces a graded course of four years of nine months each. The entrance requirements are two years of college work counting toward a degree in arts in an accredited college or university. The tuition is \$75 per year; there are no other fees. The Dean is Dr. William P. Harlow. The total registration for 1913-14 was 54; graduates, 17. The thirty-third session begins Sept. 14, 1914, and ends June 9, 1915.

CONNECTICUT

Connecticut, with a population of 1,114,756 has one medical college, located in New Haven, population 133,605.

Candidates for license to practice medicine in Connecticut, who graduate in 1914 or thereafter are not eligible unless, prior to entering on the study of medicine they had completed, in addition to an accredited four-year high school education, at least nine months of collegiate work including college courses in physics, chemistry and general biology.

New Haven

YALE MEDICAL SCHOOL, York and Chapel Streets.—This is the Department of Medicine of Yale University. In 1810 a charter was granted for the establishment of this school, and in 1813 it was organized as the Medical Institution of Yale College. The first class graduated in 1814. The faculty consists of 16 professors and 50 lecturers and assistants, a total of 66. The requirement for admission is two full years of collegiate work plus evidence of satisfactory preparation in physics, general inorganic chemistry and general biology. The course covers four years of nine months each. The fees for the four years, respectively, are approximately \$223, \$170, \$153 and \$163. The Dean is Dr. George Blumer. The total registration for 1913-14 was 49; graduates, 8. The one hundred and second session begins Oct. 1, 1914, and ends June 23, 1915.

DISTRICT OF COLUMBIA

Washington, population 331,069, has three medical colleges; George Washington University Medical School, Georgetown University School of Medicine and Howard University School of Medicine.

Washington

GEORGE WASHINGTON UNIVERSITY MEDICAL SCHOOL, 1325 H Street, N.W.—Organized in 1822 as the National Medical College, Medical Department of Columbian College. Classes were graduated in 1826 and in all subsequent years, except 1834 to 1838, and 1861 to 1863, inclusive.

The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904, by an act of Congress, the title of George Washington University was granted to the institution. The faculty is composed of 22 professors and 51 instructors, demonstrators and assistants, a total of 73. One year of collegiate work is required for admission. The course covers four years of thirty-two weeks each. The total fees are \$150 per year. The Dean is Dr. William C. Borden. The total registration for 1913-14 was 171; graduates, 16. The ninety-third session begins Sept. 30, 1914, and ends June 9, 1915.

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE, 920 H Street, N.W.—Organized in 1851. The first class graduated in 1852. The faculty contains 33 professors, 54 instructors and assistants; total, 87. Two years of collegiate work are required for entrance. The course of study covers four terms of eight and one-half months each. The fees for the first year are \$165, and for each of the other three years, \$150. The Dean is Dr. George M. Kober. The registration for 1913-14 was 99; graduates, 21. The sixty-fourth session begins Sept. 25, 1914, and ends June 13, 1915.

HOWARD UNIVERSITY SCHOOL OF MEDICINE, Fifth and W Streets, N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Colored students compose a majority of those in attendance. The faculty comprises 19 professors and 20 lecturers and assistants, 39 in all. The admission requirements are one year of collegiate work including physics, chemistry, botany and zoology and a reading knowledge of one modern language besides English. The course covers four years of thirty-two weeks each. The fees of each of the four sessions, respectively, are \$107, \$102, \$102 and \$109. The Dean is Dr. Edward A. Balloch. Registration for 1913-14 was 110; graduates, 32. The forty-seventh session begins Oct. 1, 1914, and ends June 2, 1915.

GEORGIA

Georgia, population 2,609,121, has two medical colleges; University of Georgia, Medical Department, located in Augusta, population 41,040 and the Atlanta Medical College, in Atlanta, a city of 154,839 population.

Atlanta

ATLANTA MEDICAL COLLEGE.—Butler and Armstrong Streets.—Organized in 1854. Classes graduated, 1855 to 1861, when it suspended. Reorganized in 1865. In 1898 it merged with the Southern Medical College (organized in 1878) taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with the Atlanta School of Medicine (organized in 1905), reassuming its first title. One year of collegiate work is required for entrance. It has a faculty of 34 professors and 78 instructors, assistants, etc., a total of 113. The course of study is four years of thirty-two weeks each. The fees are \$150 each year. The Dean is Dr. W. S. Elkin. Total registration for 1913-14 was 488; graduates, 125. The next session begins Sept. 28, 1914, and ends June 1, 1915.

Augusta

UNIVERSITY OF GEORGIA, MEDICAL DEPARTMENT, Railroad Avenue and Harper Street.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. Since 1873 it has been known as the Medical Department of the University of Georgia. Entire property transferred to the University in 1911. Classes were graduated in 1833 and in all subsequent years except 1862 and 1863. The faculty includes 20 professors and 27 assistants, 47 in all. One year of collegiate work is required for entrance. The course is four years of thirty-four weeks each. Fees are \$150 each year. The Dean is Dr. W. H. Doughty, Jr. The total registration for 1913-14 was 58; graduates, 20. The eighty-third session begins Sept. 16, 1914, and ends June 1, 1915.

ILLINOIS

Illinois, population 5,638,591, has eight medical colleges, two of which give instruction at night, all located in Chicago, a city of 2,185,283 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, University of Illinois College of Medicine, Hahnemann Medical College and Hospital, Bennett Medical College, Chicago College of Medicine and Surgery, Jenner Medical College and the Chicago Hospital College of Medicine.

To be eligible for license to practice medicine in Illinois, students matriculating in the session of 1914-15 and thereafter, in addition to an accredited four-year high school education, must have completed at least a year of collegiate work including courses in physics, chemistry, biology and a modern language, to be taken either in a preliminary year given by a recognized medical college, or in an approved college of liberal arts.

Chicago

RUSH MEDICAL COLLEGE.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 until 1898, when it became affiliated with the University of Chicago. The first class graduated in 1844. The faculty is composed of 100 professors, 188 associates, instructors, etc., a total of 288. The requirements for admission are two years of college work, including knowledge of college chemistry, physics and biology, and a reading knowledge of German or French. Classes are limited to 100 students in each of the freshman and sophomore classes and to 120 students in each of the clinical years. No application for admission is accepted after September 1. The course covers four years of eight and a half months each. A fifth year, consisting of a hospital internship or of a fellowship in one of the departments, will be required of all students matriculating for the summer quarter of 1914 and thereafter. All freshmen and sophomore studies are given at the University of Chicago. The clinical years are given in the building at the corner of Wood and Harrison Streets. The total fees are \$180 each year. A matriculation fee of \$5 is paid but once, and there are incidentals amounting from \$2 to \$5 annually. The

Dean is Dr. John M. Dodson. Total registration 1913-14 was 462; graduates, 97. The seventy-second session begins Oct. 1, 1914, and ends June 19, 1915.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, South Dearborn Street, between Twenty-Fourth and Twenty-Fifth Streets.—Organized in 1859 as the Medical Department of Lind University. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869, but retained the name of Chicago Medical College until 1891, when the present name was taken. The faculty comprises 58 professors and 80 lecturers and assistants, a total of 138. The requirements for admission are such as will admit to the College of Liberal Arts of Northwestern University plus two years of college work including courses in physics, chemistry, biology and a modern language. The course covers four years of eight months each. The fees for the four years, respectively, are \$190, \$195, \$190 and \$206. The Dean is Dr. Arthur R. Edwards. The total registration for 1913-14 was 180; graduates, 69. The fifty-fifth session begins Sept. 29, 1914, and ends June 6, 1915.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE, Honore and Congress Streets.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1896 and an integral part in 1910. The relationship with the university was canceled in June, 1912, but restored in March, 1913. The American Medical Missionary College was absorbed in 1910. Two years of collegiate work are required for admission. The faculty is composed of 60 professors, 89 assistants and instructors, a total of 149. The fees are \$155 each year. The Dean is Dr. D. A. K. Steele. Total registration for 1913-14 was 422; graduates, 113. The thirty-third session begins Oct. 1, 1914, and ends June 11, 1915.

CHICAGO COLLEGE OF MEDICINE AND SURGERY, 706 South Lincoln Street.—Organized in 1901 as the American College of Medicine and Surgery (Chicago Eclectic Medical College). The latter part of the name was dropped in 1902 and it became the Medical Department of Valparaiso University. Eclecticism was dropped in 1905. The name was changed to the above in 1907. One year of collegiate work, including courses in physics, chemistry, biology and a modern language is required for admission. The course covers four years of eight months each. The faculty numbers 114. The total fees of each of the four years are \$150. The Dean is Dr. W. J. Butler. The total registration for 1913-14 was 638; graduates 177. The fourteenth session begins Sept. 29, 1914, and ends May 24, 1915.

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL OF CHICAGO, 2811 Cottage Grove Avenue.—Organized in 1859. The first class was graduated in 1861. The faculty includes 32 professors and 46 lecturers, assistants, etc., a total of 78. One year of collegiate work, including courses in physics, chemistry and biology and a modern language is required for admission. The course extends over four years of eight months each. The tuition fees for the four years, respectively, are \$146, \$131.50, \$165 and \$186.50. The Dean is Dr. Joseph P. Cobb. The total registration for 1913-14 was 92; graduates, 17. The fifty-fifth session begins Sept. 28, 1914, and ends May 27, 1915.

BENNETT MEDICAL COLLEGE, Fulton and Ada Streets.—Organized in 1868 as the Bennett College of Eclectic Medicine and Surgery. Dropped Eclecticism in 1909. In 1910 it united with the Illinois Medical College and became by affiliation the Medical Department of Loyola University. The first class graduated in 1870. The faculty numbers 68. The course covers five years of thirty-two weeks each. The fees are \$150 each year. The Dean is Dr. Maximilian Herzog. The total registration for 1913-14 was 406; graduates, 111. The next session begins Sept. 30, 1914, and ends May 28, 1915.

JENNER MEDICAL COLLEGE, an afternoon and night school, located at 701 South Wood Street.—Organized in 1892. Classes were graduated in 1896 and in all subsequent years. The faculty numbers 48. The Secretary is Dr. John D. MacKellar. Total registration for 1913-14 was 199; graduates, 11. The next session begins Sept. 1, 1914, and ends June 13, 1915. *Reported not recognized by the licensing boards of thirty-one states.*

CHICAGO HOSPITAL COLLEGE OF MEDICINE, another afternoon and night school, located at 3832 Rhodes Avenue.—Organized in 1913. Claimed to have had a registration of 75 in 1913-14. There was 1 graduate. *Official reports indicate that the diplomas from this college are not recognized by the licensing boards of thirty-one states.*

INDIANA

Indiana, population 2,700,876, has one medical college, the Indiana University School of Medicine, located at Indianapolis, a city of 233,650 people, except that the work of the first year is offered also at Bloomington, the seat of the University.

Candidates for license to practice medicine in Indiana who matriculated between Jan. 11, 1910 and Jan. 11, 1914, must have completed one year of collegiate work in addition to an accredited four-year high school course prior to beginning the study of medicine. Those matriculating subsequent to Jan. 11, 1914, must have completed two years of work in a recognized college of liberal arts. This additional preliminary work must have included college courses in physics, chemistry and biology.

Bloomington and Indianapolis

INDIANA UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1903, but did not give all of the work of the first two years of the medical course until 1905. In 1907 by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1869), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. The faculty consists of 72 professors and 58 lecturers, associates and assistants, a total of 130. Two years of collegiate work are required for admission. The work of the first year is emphasized only at Bloomington. The work of the other three years is all at Indianapolis. The fees for the four years, respectively, are \$100, \$100, \$130 and \$130. A fifth optional year leading to the "M.D. cum

laude" has been added. The Secretary at Bloomington is Dr. B. D. Myers; the Dean is Dr. Charles P. Emerson, Indianapolis. The total registration for 1913-14 was 133; graduates, 22. The next session begins Sept. 29, 1914, and ends June 23, 1915.

IOWA

Iowa, population 2,224,771, has two medical colleges. The College of Medicine and the College of Homeopathic Medicine of the State University of Iowa, both located in Iowa City, population 10,091.

Candidates for license to practice medicine in Iowa who graduated subsequent to Jan. 1, 1911, must have completed two years of work in an approved college of liberal arts prior to beginning the study of medicine, this preliminary college work to have included courses in physics, chemistry and biology.

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE. University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. The faculty is made up of 21 professors, 21 lecturers, demonstrators and assistants, a total of 42. Two years of collegiate work, including courses in physics, chemistry, biology and French or German, are required for admission. The course of study covers four years of thirty-six weeks each. Total fees for each of the four years, respectively, are \$110, \$100, \$100 and \$110. The Dean is Dr. Lee Wallace Dean, Iowa City. Total registration for 1913-14 was 108; graduates, 13. The forty-fifth session begins Sept. 21, 1914, and ends June 16, 1915.

STATE UNIVERSITY OF IOWA COLLEGE OF HOMEOPATHIC MEDICINE.—Organized in 1877. The first class graduated in 1878. The faculty is composed of 15 professors and 15 lecturers and assistants, a total of 30. The work of the first two years is taken in classes with the students of the College of Medicine of the State University of Iowa, and it has the same entrance requirements. The fees are \$100 each year, plus a matriculation fee of \$10, paid but once, and a graduation fee of \$10. The Dean is Dr. George Royal. Total registration for 1913-14 was 5; no graduates. The thirty-seventh session begins Sept. 21, 1914, and ends June 16, 1915.

KANSAS

Population 1,690,949, has one medical college. The School of Medicine of the University of Kansas gives its first two years in Lawrence, population 12,915, and the last two years in Rosedale, a suburb of the two Kansas Cities, which together have a population of 330,662.

Candidates for license to practice medicine in Kansas who matriculated in the session of 1910-11 and thereafter must present credentials showing that he matriculated in and graduated from a medical college which required for admission at least one year of collegiate work including college courses in physics, chemistry and biology in addition to an accredited four-year high school course. This applies to all graduates of 1914 and thereafter.

Lawrence and Rosedale

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE.—Organized in 1880. In 1905 it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1877. Absorbed Kansas Medical College in 1913. The faculty, including lecturers and clinical assistants, numbers 53. The requirements for admission are two years of collegiate work. The course covers four years of nine months each. The total fees are for each of the first two years, \$30 per year (and for non-residents of the state, \$45); for the last two years \$100 and \$105, respectively. The Dean is Dr. S. J. Crumline; Associate Dean, Dr. M. I. Sudler. The total registration for 1913-14 was 105; graduates, 10. The thirty-fifth session begins Sept. 16, 1914, and ends June 10, 1915.

KENTUCKY

Kentucky, population 2,289,905, has one medical college, the University of Louisville Medical Department, situated in Louisville, a city of 223,928 inhabitants.

To be eligible for license to practice medicine in Kentucky all students matriculating in and after the session of 1914-15 must have completed, in addition to an accredited four-year high school course, at least one year's work in an approved college of liberal arts including college courses in physics, chemistry, biology and a modern language.

Louisville

UNIVERSITY OF LOUISVILLE MEDICAL DEPARTMENT, First and Chestnut Streets.—Organized in 1837 as the Louisville Medical Institute. The first class graduated in 1838, and a class graduated in each subsequent year except in 1863. In 1846 the present name was assumed. In 1907 it absorbed the Kentucky University Medical Department. In 1908 it absorbed the Louisville Medical College, the hospital College of Medicine and the Kentucky School of Medicine. One year of collegiate work is required for admission. It has a faculty of 35 professors and 58 lecturers and assistants, a total of 93. The course covers four years of thirty-two weeks each. The fees are \$165 each year; graduation fee \$10. The Dean is Dr. Henry Enos Tuley. The total registration for 1913-14 was 273, graduates, 54. The next session begins Sept. 28, 1914, and ends June 3, 1915.

LOUISIANA

Louisiana, having a population of 1,656,388, contains one medical college, the School of Medicine of the Tulane University of Louisiana, situated in New Orleans, a city of 339,075.

New Orleans

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE, University Campus and 1551 Canal Street.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years, except 1863-65, inclusive. It was transferred to Medical Department of the University of Louisiana in 1847 and became the Medical Department of the Tulane University in 1884. Present name in 1913 when it became the School of Medicine of the College of Medicine of the Tulane University. The faculty has 29 professors and 86 instructors, demonstrators, etc., a total of 115. The course covers four years of thirty-two weeks each. One year of collegiate work is required for admission. Total fees are \$195 per year; graduation fee, \$30. The Dean is Dr. Isadore Dyer. The total registration for 1913-14 was 327; graduates, 77. The eighty-first session begins Sept. 28, 1914, and ends June 2, 1915.

MAINE

Maine, population 742,371, has one medical college, located in Brunswick and Portland, the latter having a population of 58,571.

Brunswick-Portland

MEDICAL SCHOOL OF MAINE. The medical department of Bowdoin College. The first two years are given at Bowdoin College, Brunswick, the last two at Portland, building located on Chadwick Street.—Organized in 1820. The first class graduated in 1820. The faculty numbers 66. The course covers four years of eight months each. The total fees are \$110 for each of the first three years and \$135 for the fourth. The Dean is Dr. Addison S. Thayer, 10 Deering Street, Portland. The total number of students in 1913-14 was 67; graduates, 19. Ninety-fourth session begins Oct. 15, 1914, and ends June 24,

MARYLAND

Maryland, with a population of 1,295,346, contains three medical colleges, all located in Baltimore, a city with 558,485 inhabitants. They are as follows: Johns Hopkins University Medical Department, School of Medicine of the University of Maryland and the College of Physicians and Surgeons.

BOSTON UNIVERSITY SCHOOL OF MEDICINE, 80 East Concord Street.—Organized in 1873. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class graduated in 1874. One year of collegiate work is required for admission. The faculty includes 33 professors, 35 associates, etc., a total of 68. The course covers four years of eight months each. Total fees for each of the four years, respectively, are \$152, \$147, \$127 and \$155. The Dean is Dr. John P. Sutherland. Total registration for 1913-14 was 113; graduates, 22. The forty-second session begins Oct. 1, 1914, and ends June 2, 1915.

TUFTS COLLEGE MEDICAL SCHOOL, 416 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. It has a faculty of 42 professors and 80 assistants, lecturers, etc., a total of 122. One year of collegiate work is required for admission. The course covers four years of eight months each. The total fees are \$155 each year. The Dean is Dr. Charles F. Painter. Total registration for 1913-14 was 311; graduates, 62. The twenty-first session begins Sept. 30, 1914, and ends June 1, 1915.

COLLEGE OF PHYSICIANS AND SURGEONS, 517 Shawmut Avenue.—Organized in 1880. The first class graduated in 1882. The college announcement gives the names of 228 "matriculants and applicants" for the session of 1913-14, which included both dental and medical students. Fairly reliable information, however, shows that the total attendance of medical students during 1913-14 was 110. There were 13 graduates. This college has been reported not recognized by the Massachusetts Medical Society and by the licensing boards of thirty-one states.

MICHIGAN

Michigan, population 2,810,173, has three medical colleges. Two of these, the University of Michigan Department of Medicine and Surgery and the Homeopathic Medical College of the University of Michigan, are located at Ann Arbor, a city of 14,817 people. The Detroit College of Medicine and Surgery is located at Detroit, a city of 465,766 inhabitants.

To be eligible for license to practice medicine in Michigan, all students matriculating in and after the session of 1914-15, in addition to an accredited four-year high school education, must have completed at least one year's work in an approved college of liberal arts including college courses in physics, chemistry and biology, prior to beginning the study of medicine.

year's internship in an approved hospital. The entrance requirements are two years of university work which must include one year each of physics, general chemistry, qualitative analysis, zoology or botany, and French or German, all in addition to a four-year high school course, including two years of Latin. Students entering hereafter will be required to secure a degree of B.S. or A.B. before the M.D. is granted. Total fees are \$150 each year. The Dean is Dr. E. P. Lyon. The total registration for 1913-14 was 169; graduates, 30. The twenty-seventh session begins Sept. 16, 1914, and ends June 11, 1915.

MISSISSIPPI

Mississippi, population 1,797,114, has one medical college, the Department of Medicine of the University of Mississippi, which is located at Oxford, a city of 1,825 inhabitants.

Oxford

UNIVERSITY OF MISSISSIPPI DEPARTMENT OF MEDICINE.—Organized in 1903. Gives only the first two years of the medical course. The session extends over eight and a half months. Entrance requirements are one year of collegiate work in addition to an accredited four-year high school education. The total fees each year are, respectively, \$102 and \$100. The faculty numbers 14. The Dean is Dr. W. S. Leathers. The total registration for 1913-14 was 35. The twelfth session begins Sept. 17, 1914, and ends June 1, 1915.

MISSOURI

Missouri, population 3,293,335, has seven medical colleges. St. Louis, population 687,029, contains four of these, viz., the School of Medicine of St. Louis University, Washington University Medical School, St. Louis College of Physicians and Surgeons and the American Medical College. Kansas City, which with Kansas City, Kan., has a total population of 330,662, has two colleges, namely: the Kansas City Hahnemann Medical College and the Eclectic Medical University. The School of Medicine of the University of Missouri is at Columbia, a town of 9,662 people.

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE.—Organized at St. Louis in 1845; was discontinued in 1859, but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. The faculty includes 9 professors and 6 assistant professors, lecturers, etc., a total of 15. The course covers two years of nine months each. The entrance requirements are two years of college work including English, 5 hours; German, 5 hours; general zoology, 5 hours; physics, 5 hours; inorganic chemistry, 5 hours; elective, 35 hours. Equivalent work in foreign language may be substituted for the English and German. Total fees are \$40 each year. The acting Dean is Dr. Guy L. Noyes. Total registration of students for 1913-14 was 55. The next session begins Sept. 14, 1914, and ends June 3, 1915.

Kansas City

KANSAS CITY HAHNEMANN MEDICAL COLLEGE, 916 Tracy Avenue.—Organized in 1888 as the Kansas City Homeopathic Medical College. The first class graduated in 1899. In 1902 it united with the Hahnemann Medical College of Kansas City University, taking the present title. The faculty numbers 40. The fees are \$125 each year. The Registrar is Dr. Sam H. Snow. Total registration for 1913-14 was 46; graduates, 13. The next session begins Sept. 8, 1914, and ends May 20, 1915.

ECLECTIC MEDICAL UNIVERSITY, 1423 Independence Avenue.—Organized at Kansas City, Mo., in 1898 with the present title. Moved to Kansas City, Kan., in 1907, and took the name of Western Eclectic College of Medicine and Surgery. Returned to Kansas City, Mo., in 1909 and resumed the present title. First class graduated in 1900. The total registration for 1913-14 was 65; graduates 14. Reported not in good standing by the Missouri State Board of Health and by twenty-eight other state licensing boards.

St. Louis

WASHINGTON UNIVERSITY MEDICAL SCHOOL, Kingshighway and Euclid Avenue.—Organized in 1842 as the Medical Department of St. Louis University. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. The first class graduated in 1843. In 1891 it became the Washington University Medical School. In 1899 it absorbed the Missouri Medical College. The faculty comprises 23 professors and 56 lecturers, instructors, etc., a total of 79. Two full years of college work are required for admission including courses in English, physics, chemistry and biology and a reading knowledge of German. The course is four years of eight months each. The total fees for the four years are, respectively, \$155, \$150, \$150 and \$155. The Dean is Dr. Eugene L. Opie. The total registration for 1913-14 was 6; graduates, 15. The next session begins Sept. 24, 1914, and ends June 10, 1915.

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE, 1402 South Grand Avenue.—Organized in 1901 by union of Marion Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. It became the Medical Department of St. Louis University in 1903. The faculty is composed of 53 professors, 69 lecturers and assistants, a total of 122. One year of college subjects preliminary to the four years of medical subjects is given in the medical school. The curriculum covers four years of thirty-four weeks each. The total fees are \$140 each year. The total registration for 1913-14 was 204; graduates, 45. The Dean is Dr. Hanau W. Loeb. The next session begins Sept. 15, 1914, and ends May 17, 1915.

ST. LOUIS COLLEGE OF PHYSICIANS AND SURGEONS, Jefferson Avenue and Gamble Street.—Organized in 1869. Classes graduated in 1870 and each subsequent year until 1873, when it suspended. It was reorganized in 1879. Classes graduated in 1880 and subsequent years. Total registration for 1913-14 was 48; graduates, 24.

AMERICAN MEDICAL COLLEGE, Garrison and Lawton Avenues.—Organized in 1873 as an Eclectic College. Eclecticism dropped in 1910. Absorbed the Barnes Medical College in 1911. Became the Medical

Department of the National University of Arts and Sciences in 1912. Two classes were graduated each year from 1874 to 1883, inclusive. Since then one class has graduated each year. The course covers four years of eight and a half months each. Beginning with the session of 1914-15 a five-year course will be required including a preliminary year in physics, chemistry and biology. Fees: matriculation, \$5; tuition each year, \$135. The Dean is Dr. James Moores Ball. The total registration for 1913-14 was 146; graduates, 34. The next session begins Sept. 22, 1914, and ends June 7, 1915.

NEBRASKA

Nebraska, population 1,192,214, has three medical colleges. The University of Nebraska College of Medicine and the John A. Creighton Medical College of Omaha, population 124,096, and the Cotner University Medical College at Lincoln, population 43,973.

Bethany-Lincoln

COTNER UNIVERSITY MEDICAL COLLEGE, Eclectic. University Campus Bethany, and corner Thirtieth and P Streets, Lincoln. It is the Medical Department of Cotner University.—Organized in 1890 as the Lincoln Medical College. Assumed present title in 1911. The first class graduated in 1891. The faculty numbers 33. The fees are \$100 each year. The Registrar is Prof. R. L. Huff, Lincoln. The total registration for 1913-14 was 29; graduates, 5. The next session begins Sept. 14, 1914, and ends May 27, 1915.

Omaha

JOHN A. CREIGHTON MEDICAL COLLEGE, Fourteenth and Davenport Streets. It is the Medical Department of Creighton University.—Organized in 1892. The first class graduated in 1895. It has a faculty of 15 professors and 38 associates, lecturers and assistants, a total of 53. One year of collegiate work is required for admission. The course of study embraces four years of eight months each. The total fees for the four years, respectively, are \$130, \$120, \$120 and \$120. The Dean is Dr. A. L. Muirhead. Total registration for 1913-14 was 182; graduates, 35. The twenty-third session begins Sept. 1, 1914, and ends April 30, 1915.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE, Forty-Second Street and Dewey Avenue.—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha university in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The first two years were given at Lincoln and the last two in Omaha until 1913 when all four years were transferred to Omaha. The faculty is composed of 31 professors and 27 lecturers and instructors, total 58. Two years of collegiate work are required for admission including courses in physics, chemistry, zoology and German. The fees are approximately \$100 per annum. The Secretary is Dr. Irving S. Cutler. Total registration for 1913-14 was 84; graduates, 11. The next session begins Sept. 14, 1914, and ends June 4, 1915.

NEW HAMPSHIRE

New Hampshire, population 443,140 has one medical college, located at Hanover, population 1,884.

Only graduates of medical colleges registered by the Regents of New Hampshire are eligible to obtain licenses to practice medicine. Medical colleges to be registered, for all students matriculating in the session of 1914-15 and thereafter, must require for admission at least one year of collegiate work, including college courses in physics, chemistry and biology in addition to a standard four-year high school education.

DARTMOUTH MEDICAL SCHOOL.—Organized as New Hampshire Medical Institute in 1797. The first class graduated in 1798. It is under the control of the trustees of Dartmouth College. Clinical teaching was discontinued in 1914. The faculty is made up of 19 professors and 7 instructors, a total of 26. Two years of collegiate work are required for admission. The course covers nine calendar months in each year, or eight months of actual teaching. Candidates for the B.S. degree in Dartmouth College may substitute the work of the first two years in medicine for that of the junior and senior years in the academic department. Candidates for the A.B. degree may make a similar saving of one year. The fees for the two years in medicine are, respectively, \$169.50 and \$173.50. Dean, Dr. John M. Gile; Secretary, Colin C. Stewart. The next session opens September 24, 1914, and ends June 24, 1915.

NEW YORK

New York State, population 9,113,614, has ten medical colleges. Seven of these, College of Physicians and Surgeons (Columbia University), Long Island College Hospital, New York Homeopathic Medical College and Hospital, New York Medical College and Hospital for Women, Cornell University Medical College, the University and Bellevue Hospital Medical College and Fordham University School of Medicine, are located in New York City, population 4,766,883. Albany Medical College is located in Albany, a city of 100,253 people. The University of Buffalo Medical Department is situated in Buffalo, population 423,715. The College of Medicine, Syracuse University, is in Syracuse, a city of 137,249 inhabitants.

Albany

ALBANY MEDICAL COLLEGE, Lancaster and Jay Streets.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. The faculty is composed of 18 professors and 85 lecturers, assistants, etc., a total of 103. One year of collegiate work, including college courses in physics, chemistry and

biology are required for admission. The curriculum covers four years of eight months each. The fees for each of the four years are, respectively, \$135, \$140, \$120 and \$130. The Registrar is Dr. Joseph D. Craig. The total registration for 1913-14 was 258; graduates 52. The eighty-fourth session begins Sept. 22, 1914, and ends May 25, 1915.

Buffalo

UNIVERSITY OF BUFFALO MEDICAL DEPARTMENT. High Street, near Main.—Organized in 1846. The first class graduated in 1874. It absorbed the Medical Department of Niagara University in 1898. The faculty is composed of 33 professors and 67 lecturers, assistants, etc., a total of 100. One year of collegiate work, including college courses in physics, chemistry and biology are required for admission. The course covers four years of eight months each. The total fees for the four years, respectively, are \$185, \$180, \$140 and \$140. The Dean is Dr. Herbert U. Williams. Total registration for 1913-14 was 236; graduates, 47. The sixty-ninth session begins Sept. 21, 1914, and ends June 4, 1915.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 437 West Fifty-Ninth Street.—Organized in 1807 by the regents of the University of the State of New York as their medical department. The first class graduated in 1811. Affiliated with Columbia College in 1814 and was permanently connected in 1860, when it became the Medical Department of Columbia College. That institution became Columbia University in 1891. The faculty is composed of 76 professors and 133 instructors, demonstrators, etc., a total of 209. Two years of collegiate work, including courses in physics, chemistry and biology are required for admission. The work covers four years of eight months each. The Dean is Dr. Samuel W. Lambert. The total fees for the first year are \$255; for the second and third, \$250, and \$275 for the fourth year. Total registration for 1913-14 was 308; graduates, 71. The one hundred and seventh session begins Sept. 23, 1914, and ends June 2, 1915.

CORNELL UNIVERSITY MEDICAL COLLEGE, First Avenue and Twenty-Eighth Street, New York City, and Ithaca.—Organized in 1898. The first class was graduated in 1899. The work of the first year may be taken either in Ithaca or New York. The faculty is composed of 38 professors and 99 assistants, lecturers, instructors, etc., a total of 137. All candidates for admission must be graduates of approved colleges or scientific schools or seniors of approved colleges which will permit them to substitute the first year of this medical school for the fourth year of their college course and will confer on them the Bachelor degree on the completion of the year's work. The candidate must also have such knowledge of physics, inorganic chemistry and biology as may be obtained in college by a year's course in these subjects when accompanied by laboratory work. The fees for each of the four years are, respectively, \$190, \$185, \$185 and \$200. The Dean is Dr. William M. Polk. Total registration for 1913-14 was 108; graduates, 20. The seventeenth session begins Sept. 30, 1914, and ends June 10, 1915.

FORDHAM UNIVERSITY SCHOOL OF MEDICINE, Bathgate Avenue and Fordham Road.—Organized in 1905. First class graduated in 1909. The faculty consists of 49 professors and 50 lecturers and assistants, a total of 99. The course of instruction covers four years of eight and a half months each. Fees, \$700 each year. A year's work in a recognized college of liberal arts, including college courses in physics, chemistry and biology, is required for admission. The Dean is Dr. William P. Healy. The total registration for 1913-14 was 175; graduates, 29. The tenth session begins Sept. 25, 1914, and ends June 8, 1915.

LONG ISLAND COLLEGE HOSPITAL, Henry Street, near Atlantic Avenue, Brooklyn.—Organized in 1858. The first class graduated in 1860. It has a faculty of 39 professors and 74 assistants, instructors, etc., a total of 113. A year of collegiate work including college courses in physics, chemistry and biology is required for admission. The course covers four years of eight months each. Fees: First year, \$210, second year, \$205, third, \$200, and \$200 for the fourth year. The Secretary is Dr. Joseph H. Raymond. Total registration 1913-14 was 360; graduates, 79. The fifty-seventh session begins Sept. 22, 1914, and ends June 7, 1915.

NEW YORK HOMEOPATHIC MEDICAL COLLEGE AND FLOWER HOSPITAL, Eastern Boulevard, between Sixty-Third and Sixty-Fourth Streets.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College for the State of New York. The present title was assumed in 1869. The first class graduated in 1861. The faculty consists of 27 professors and 44 assistants, lecturers, etc., a total of 71. The total fees for each of the four years respectively are \$165, \$160, \$150 and \$180. The Dean is Dr. Royal S. Copeland. Total registration for 1913-14 was 237; graduates, 43. The fifty-fifth session begins Sept. 30, 1914, and ends May 26, 1915.

NEW YORK MEDICAL COLLEGE AND HOSPITAL FOR WOMEN (Homeopathic) 17-19 West One Hundred and First Street.—Organized in 1863. The first class graduated in 1864. The faculty consists of 30 professors and 28 lecturers and assistants, a total of 58. The course covers four years of thirty weeks each. The fees for each of the four years, respectively, are \$155, \$150, \$135 and \$155. The Dean is Dr. Cornelia C. Brant. The total registration for 1913-14 was 42; graduates, 7. Matriculants are not listed in the annual announcement. The fifty-second session begins Sept. 23, 1914, and ends June 3, 1915.

UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE, First Avenue and Twenty-Sixth Street.—Organized in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. It is the Medical Department of New York University. The faculty is composed of 69 professors and 56 instructors, etc., in all 125. The course covers four years of eight months each. Entrance requirements are one year of years of college work, in addition to a standard four-year high school course, collegiate work, a addition to a standard four-year high school course, including college courses in physics, chemistry and biology. The fees are \$200 per year; graduation fee, \$25. The Secretary is Dr. Samuel A. Brown. Total registration for 1913-14 was 333; graduates, 83. The next session begins Sept. 23, 1914, and ends June 9, 1915.

Syracuse

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE, 307-311 Orange Street.—Organized in 1872, when the Geneva Medical College was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Present title assumed in 1875. The first class graduated in 1873 and a class graduated each subsequent year. In 1884 the amalgamation with the university was made complete. Two years of a recognized college course are required for admission. The course covers four years of thirty-five weeks each. The total fees for each of the four years are respectively, \$192, \$187, \$187 and \$207. The

faculty is composed of 23 professors and 50 associate and assistant professors, lecturers and instructors. The Dean is Dr. John L. Heffron. The total enrollment for 1913-14 was 96; graduates, 16. The forty-third session begins Sept. 15, 1914, and ends June 9, 1915.

NORTH CAROLINA

North Carolina, population 2,206,287, has three medical schools, all of which give only the first two years of the medical course. The School of Medicine of the University of North Carolina is located at Chapel Hill, population 1,200. The Leonard Medical School is at Raleigh, population 19,218. Wake Forest College School of Medicine is at Wake Forest, population 823.

Chapel Hill

UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE.—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department at Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. One year of collegiate work is required for admission. The faculty is composed of 12 professors and 13 lecturers, assistants, etc., a total of 25. The total fees for the two years, respectively, are \$120 and \$125. The Dean is Dr. I. H. Manning. The total registration for 1913-14 was 60. The twenty-ninth session begins Sept. 10, 1914, and ends June 2, 1915.

Raleigh

LEONARD MEDICAL SCHOOL.—Colored. This department of Shaw University was established in 1882. Classes were graduated in 1886, 1888 and in all subsequent years, including 1914 when clinical teaching was discontinued. A year of collegiate work is required for admission. It has a faculty of 14. The course covers four years of seven and a half months each. The total fees for each year are \$57; graduation fee, \$10. The Dean is Dr. George H. Stoddard. Total registration for 1913-14 was 76; graduates 8. The thirty-third session begins Sept. 30, 1914, and ends May 13, 1915.

Wake Forest

WAKE FOREST COLLEGE SCHOOL OF MEDICINE.—This school was organized in 1902. The faculty, including the professors of chemistry, physics, and biology numbers 10, exclusive of laboratory assistants. Only the first two years of the medical course are offered after the completion of freshmen and sophomore college work, and on this combined course the B.S. degree is conferred. Each annual course extends over nine months. The fees for each year aggregate \$103. The Secretary is E. B. Earnshaw. The total registration for 1913-14 was 28. The thirteenth session begins Sept. 1, 1914, and ends May 21, 1915.

NORTH DAKOTA

North Dakota, population 577,056, has one medical college, the School of Medicine of the University of North Dakota, which is situated at University, near Grand Forks, a city of 12,478 people. It gives only the first two years of the medical course.

Candidates for license to practice medicine in North Dakota who graduated in 1912 and thereafter, in addition to a four-year high school education must have completed two years of work in an approved college of liberal arts including courses in Latin, physics, chemistry, botany and zoology, prior to beginning the study of medicine.

University

UNIVERSITY OF NORTH DAKOTA SCHOOL OF MEDICINE.—Organized in 1905. The faculty is composed of 5 professors and 12 instructors, a total of 17. The course consists of two years' academic work and two years of medical college subjects, occupying nine months each year. The total fee for each of the medical years is \$50. The Dean is Dr. H. E. French. The total registration for 1913-14 was 14. The tenth session begins Sept. 22, 1914, and ends June 16, 1915.

OHIO

Ohio, population 4,767,121, has five medical colleges. Two of these, the Medical College of the University of Cincinnati and the Eclectic Medical College, are located in Cincinnati, a city of 364,463 inhabitants. Cleveland, population 560,663, contains one medical school, Western Reserve University School of Medicine. Columbus, population 181,548, contains one medical college, the Ohio State University College of Medicine.

Cincinnati

THE MEDICAL COLLEGE OF THE UNIVERSITY OF CINCINNATI, Clifton Avenue, west of Vine Street.—Organized in 1909 by the union of the Ohio Medical College (founded in 1819) with the Miami Medical College (founded in 1852). The Ohio Medical College became the Medical Department of the University of Cincinnati, April 26, 1896. Under a similar agreement, March 2, 1909, the Miami Medical College also merged into the University, when the title of Ohio-Miami Medical College of the University of Cincinnati was taken. The faculty consists of 37 professors, 100 associates, assistants, etc., a total of 137. Two years of college work are required for admission. The course covers four years of eight months each. The fees are a tuition fee of \$150 a year; a matriculation fee of \$5, payable but once, and a graduation fee of \$25. The Dean is Dr. Christian R. Holmes. The total registration for 1913-14 was 60; graduates, 14. The next session begins Sept. 29, 1914, and ends June 12, 1915.

ELECTIC MEDICAL COLLEGE, 630 West Sixth Street.—Organized in 1833 at Worthington as the Worthington Medical College. Removed to Cincinnati in 1843. In 1845 it was chartered as the Eclectic Medical Institute. In 1857 the American Medical College, organized in 1839, was merged into it, and in 1859 the Eclectic College of Medicine and Surgery, organized in 1856, merged into it. In 1910 it assumed its present title. Classes were graduated in 1833 and in all subsequent years except 1839 to 1843, inclusive. It has a faculty of 23 professors and 12 lecturers and assistants, a total of 35. The course covers four years of eight months each. The fees are \$120 for each year. The Secretary is Dr. John K. Scudder. Total registration for 1913-14 was 87; graduates, 19. The next session begins Sept. 10, 1914, and ends May 10, 1915.

Cleveland

CLEVELAND-PULTE MEDICAL COLLEGE, Prospect Avenue and Huron Road.—Homeopathic.—Organized in 1849 as the Western College of Homeopathic Medicine. The first class graduated in 1853. In 1857 it became the Western Homeopathic College and in 1870 it became the Homeopathic Hospital College when the Homeopathic Medical College for Women, organized in 1868, merged into it. In 1894 it became the Cleveland University of Medicine and Surgery. In 1898 it merged with the Cleveland Medical College, organized in 1890, and assumed the title of Cleveland Homeopathic Medical College. In 1910 Pulte Medical College of Cincinnati merged into it and the present title was assumed. Total registration for 1913-14 was 53; graduates, 11. It is reported that this college has been transferred to the Ohio State University at Columbus where the establishing of a homeopathic college is contemplated.

WESTERN RESERVE UNIVERSITY SCHOOL OF MEDICINE, 1355 East Ninth Street.—Organized in 1843 as the Cleveland Medical College. The first class graduated in 1844. It assumed the present title in 1881. In 1910 it absorbed the Cleveland College of Physicians and Surgeons. The faculty includes 44 professors and 53 lecturers, assistants, etc., a total of 97. The curriculum embraces four years of eight and one-half months each. Three years of college work are required for admission. The total fees for each of the four years are, respectively, \$162, \$153, \$150 and \$155. The Secretary is Dr. F. C. Waite. The total registration for 1913-14 was 157; graduates, 34. The twenty-second session begins Oct. 1, 1914, and ends June 17, 1915.

Columbus

OHIO STATE UNIVERSITY COLLEGE OF MEDICINE—Buttles Avenue and Park Street.—Organized in 1907 as the Starling-Ohio Medical College by the union of Starling Medical College (organized 1834) with the Ohio Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. The faculty consists of 38 professors and 38 lecturers, demonstrators, etc., a total of 76. One year of collegiate work is required for admission. Beginning with the session of 1915-16, two years of collegiate work will be required. The course covers four years of eight months each. Matriculation, \$5; tuition of \$150 each year. The Dean is Dr. W. J. Means. The total registration for 1913-14 was 284; graduates 54. The next session begins Sept. 16, 1914, and ends June 1, 1915.

OKLAHOMA

Oklahoma, population 1,657,155, has one medical college, the School of Medicine of the University of Oklahoma. The work of the first and second years is given in the academic laboratories at Norman, a city of 3,040 inhabitants. The work of the third and fourth years is given in Oklahoma City, which has a population of 64,205 and which is eighteen miles north of Norman.

Norman and Oklahoma City

UNIVERSITY OF OKLAHOMA SCHOOL OF MEDICINE—Organized in 1900. Gave only the first two years of the medical course until 1910, when a clinical department was established at Oklahoma City. It has a faculty of 17 professors and 73 instructors, a total of 90. The course is four years of nine months each. An optional course of six years is offered for the degrees of B.S. and M.D. The total fees for the four years are, respectively, \$55, \$28, \$100 and \$105. The Dean is Dr. Curtis R. Day, 317 East Fourth Street, Oklahoma City. The total registration for 1913-14 was 94; graduates, 14. The fifteenth session begins Sept. 22, 1914, and ends June 10, 1915.

OREGON

Oregon, population 672,765, has one medical college, the University of Oregon Department of Medicine located in Portland, a city of 207,214 population.

Portland

UNIVERSITY OF OREGON DEPARTMENT OF MEDICINE, Lovejoy and Twenty-Third Streets.—Organized in 1887. The first class graduated in 1888. The Willamette University Medical Department was merged in 1913. It has a faculty of 19 professors and 43 lecturers, assistants, etc., a total of 62. Entrance requirements are one year of college work or its equivalent. The course is four years of eight months each. Fees: Matriculation, \$5; tuition, \$150 each year. The Dean is Dr. K. A. J. Mackenzie. The total registration for 1913-14 was 79; graduates, 26. The twenty-eighth session begins Oct. 1, 1914, and ends June 1, 1915.

PENNSYLVANIA

Pennsylvania, population 7,665,111, has seven medical colleges. Of these Philadelphia, having a population of 1,599,008, contains six, as follows: University of Pennsylvania School of Medicine, Jefferson Medical College, Hahnemann Medical College and Hospital, Woman's Medical Col-

lege of Pennsylvania, Medico-Chirurgical College of Philadelphia and Temple University Department of Medicine. The other school, the School of Medicine of the University of Pittsburgh, is situated in Pittsburgh, a city of 533,905.

To be eligible for license to practice medicine in Pennsylvania, students matriculating in the session of 1914-15 and thereafter, in addition to a four-year high school education must have completed a year's work either in an approved college of liberal arts or in a preliminary year in the medical college, including college courses in physics, chemistry and biology, before beginning the study of medicine. He must also have completed an internship of at least one year in an approved hospital.

Philadelphia

UNIVERSITY OF PENNSYLVANIA SCHOOL OF MEDICINE, Thirty-Sixth Street and Hamilton Walk.—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772-79, inclusive. The original title was the Department of Medicine, College of Philadelphia, which was changed to the present title in 1791. It granted the first medical diploma issued in America. The faculty is made up of 35 professors, associate, adjunct and assistant professors and 139 demonstrators, lecturers, associates, instructors, etc., a total of 174. The course embraces study of four years of thirty-four weeks each. The total fees for each of the four years are, respectively, \$229.50, \$211.50, \$210 and \$213. The Dean is Dr. William Pepper. Total registration for 1913-14 was 266; graduates, 74. The one hundred forty-third session begins Sept. 25, 1914, and ends June 16, 1915.

JEFFERSON MEDICAL COLLEGE, Tenth and Walnut Streets.—Organized in 1825 as the Medical Department of Jefferson College, Cannonsburg. The first class graduated in 1826. The present title was assumed in 1838. It has a faculty of 27 professors and 130 lecturers, demonstrators, etc., a total of 157. Entrance requirements are a completed course in a standard secondary school and in addition a preliminary year devoted to college courses in physics, chemistry and biology. The course of study covers graded work of four years of eight and a half months each. The tuition is \$200 a year, with a matriculation fee of \$5, paid but once. The Subdean is Dr. Ross V. Patterson. The total registration for 1913-14 was 648; graduates, 147. The ninetieth session begins Sept. 24, 1914, and ends June 5, 1915.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA, Cherry Street, between Seventeenth and Eighteenth Streets.—Organized in 1881. The first class graduated in 1882. The faculty is composed of 45 professors and 69 lecturers, assistants, etc., a total of 114. Entrance requirements are a completed course in a standard secondary school and in addition a preliminary year devoted to college courses in physics, chemistry and biology. The work embraces four years of eight months each. The fees for each of the four years are, respectively, \$162.50, \$159, \$155.50 and \$153. The Dean is Dr. Seneca Egbert. The total registration for 1913-14 was 350; graduates, 75. The thirty-fourth session begins Sept. 21, 1914, and ends June 4, 1915.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, Twenty-First and N. College Avenue. Organized in 1850. Classes were graduated in 1851 and in all subsequent years except 1861 and 1862. It has a faculty of 11 professors and 50 assistants, lecturers, etc., in all 61. Entrance requirements are a completed course in a standard secondary school and in addition a preliminary year devoted to college courses in physics, chemistry and biology. Beginning in 1915 this requirement will be further increased to two years of collegiate work. The curriculum covers four years of eight months each. Fees for each of the four years are, respectively, \$187, \$181, \$178.50, \$179.50. The Dean is Dr. Clara Marshall. The total registration for 1913-14 was 93; graduates, 18. The sixty-fifth session begins Sept. 16, 1914, and ends June 2, 1915.

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL, 226 North Broad Street.—Organized in 1848 as the Homeopathic Medical College of Pennsylvania. In 1869 it united with the Hahnemann Medical College of Philadelphia, taking the present title. The first class graduated in 1849. Entrance requirements are a completed course in a standard secondary school and in addition a preliminary year devoted to college courses in physics, chemistry and biology. It has a faculty of 36 professors and 53 lecturers, instructors, etc., in all 89. The work covers four years of eight and a half months each. Fees: For each year, \$180; matriculation, \$5; laboratory fee, \$10. The Dean is Dr. William A. Pearson. The total registration for the college year 1913-14 was 93; graduates, 14. The sixty-seventh session begins Sept. 21, 1914, and ends June 3, 1915.

THE TEMPLE UNIVERSITY DEPARTMENT OF MEDICINE, Eighteenth and Buttonwood Streets.—Organized in 1901. The first class graduated in 1904. The faculty numbers 97. It gives a five-year day course. The fees are \$150 per year. The Dean is Dr. Frank C. Hammond. The total registration for 1913-14 was 101; graduates, 18. The fourteenth session begins Sept. 17, 1914, and ends June 5, 1915.

Pittsburgh

UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE, Grant Boulevard.—Organized in 1886 as the Western Pennsylvania Medical College and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. The faculty is composed of 16 professors and 79 associates, assistants, etc., 95 in all. Entrance requirements are two years of recognized college work, to have included essentially courses in chemistry (inorganic and organic), physics, biology and German or French, based on a four-year high school preparation. It is possible for students to get the degree of B.S. and M.D. in six years. The course of study for medicine alone is four years of eight and a half months each. The tuition is \$220 a year, \$210 if paid in advance. The Dean is Dr. Thomas S. Arbuthnot. The total registration for 1913-14 was 124; graduates, 46. The twenty-ninth session begins Sept. 28, 1914, and ends June 16, 1915.

SOUTH CAROLINA

South Carolina, population 1,515,400, has one medical college, situated in Charleston, a city of 58,833 people.

Charleston

THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, Queen and Franklin Streets.—Founded in 1823 as the Medical College of South Carolina. In 1832 it was chartered with the present title. Classes were graduated in 1825 and in all subsequent years except 1861 to 1865, inclusive. In 1912 by legislative enactment it became a state institution. It has a faculty of 29 professors and 33 lecturers, instructors, etc., a total of 62. The course covers four years of eight months each. One year of collegiate work including courses in physics, chemistry and biology is required for admission in addition to a standard high school preparation. The total fees are \$140 each year. The Dean is Dr. Robert Wilson, Jr. Total enrollment for 1913-14 was 104; graduates, 19. The eighty-sixth session begins Oct. 1, 1914, and ends June 3, 1915.

SOUTH DAKOTA

South Dakota, population 583,888, has one medical college, the University of South Dakota College of Medicine, located at Vermilion, a city of 2,147 people.

To be eligible for license to practice medicine in South Dakota graduates of 1915 and thereafter must show that they matriculated in and graduated from medical colleges which required at least two years of collegiate work for admission, including courses in physics, chemistry, biology and a modern language. This affects all students who matriculated in the session of 1911-12 and thereafter.

Vermilion

UNIVERSITY OF SOUTH DAKOTA COLLEGE OF MEDICINE.—Organized in 1907. Offers only the first two years of the medical course. Two years' work in a college of liberal arts is required for admission. The fees are \$60 each year. The faculty numbers 9. The Dean is Christian P. Lommen, B.S. The total registration for 1913-14 was 14. The eighth session begins Sept. 15, 1914, and ends June 10, 1915.

TENNESSEE

Tennessee, population 2,184,789, has four medical colleges. Of these Vanderbilt University Medical Department and Meharry Medical College are situated in Nashville, a city with a population of 106,476. The College of Medicine of the University of Tennessee and the University of West Tennessee College of Medicine and Surgery are located in Memphis, population 136,363.

Memphis

UNIVERSITY OF TENNESSEE COLLEGE OF MEDICINE, three buildings, 879 Madison Avenue, 880 Monroe Avenue, and 718 Union Avenue.—Organized in 1876 at Nashville as Nashville Medical College. Became Medical Department University of Tennessee 1878. First class graduated 1879 and a class graduated each subsequent year. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The Trustees of the University of Nashville by formal action of that Board named the University of Tennessee College of Medicine as its legal successor in medical teaching, transferring all of its college and hospital equipment to the successor. This college then removed to Memphis, where it united with the College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913. Entrance requirements are a completed secondary education plus one year of collegiate work. The fees are \$100 per year for bona fide residents of the state and \$125 per year for non-residents; graduation fee \$25. The Dean is Dr. Herbert Thomas Brooks. Total registration 1913-14, 321; graduates, 77. The next session begins Sept. 22, 1914, and ends June 4, 1915.

UNIVERSITY OF WEST TENNESSEE COLLEGE OF MEDICINE AND SURGERY. Colored. 1190 South Phillips Place.—Organized in 1900. The first class graduated in 1904 and a class graduated each subsequent year. It has a faculty of 21. The course is four years of thirty weeks each. The fees are \$55 per year; graduation \$10 extra. The Dean is Dr. M. V. Lynk. Registration for 1913-14 was 73; graduates, 25. The fifteenth session begins Sept. 14, 1914, and ends May 1, 1915.

Nashville

VANDERBILT UNIVERSITY MEDICAL DEPARTMENT.—This school was founded in 1874. The first class graduated in 1875. The faculty consists of 25 professors and 40 lecturers, a total of 65. One year of collegiate work is required for admission. The course covers four years of nearly eight months each. The total fees for each of the first three years are \$150, and for the fourth year, \$175. The Acting Dean is Dr. L. E. Burch. The total registration for 1913-14 was 381; graduates, 65. The forty-first session begins Sept. 16, 1914, and ends June 16, 1915.

MEHARRY MEDICAL COLLEGE. Colored. Maple and Chestnut Streets.—This school was organized in 1876 and is the Medical Department of Walden University. The faculty is made up of 13 professors and 15 instructors, demonstrators, etc., 28 in all. The work embraces four years of thirty weeks each. The total fees for each of the first three years are \$70 and for the fourth year, \$80. The Dean is Dr. G. W. Hubbard. Total registration for 1913-14 was 359; graduates, 73. The thirty-ninth session begins Sept. 9, 1914, and ends April 20, 1915.

TEXAS

Texas, population 3,096,542 has four medical colleges. The University of Texas Department of Medicine is located at Galveston, a city of 36,981 inhabitants. The Texas Christian University School of Medicine is at Fort Worth, population 73,312. The Baylor University College of Medicine and the Southern Methodist University Medical Department are situated in Dallas, population 92,104.

Dallas

BAYLOR UNIVERSITY COLLEGE OF MEDICINE, 720 College Avenue.—Organized in 1900 as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University at Waco. It acquired the charter of Dallas Medical College in 1904. The first class graduated in 1901. The faculty numbers 46. Entrance requirement is one year of college work in addition to a four-year high school education. The course is four years of eight months each. The fees are \$115 each year; matriculation fee of \$5, paid in advance, \$15. The Dean is Dr. E. H. Cary. Total registration for 1913-14 was 50; graduates, 18. The fifteenth session begins Sept. 4, 1914, and ends May 31, 1915.

SOUTHERN METHODIST UNIVERSITY MEDICAL DEPARTMENT.—Organized in 1903 as the Southwestern University Medical College. Name changed as above in 1912. The first class graduated in 1904. It has a faculty of 13 professors and 25 instructors, assistants, etc., a total of 38. The course of instruction covers four years of eight months each. One year of collegiate work in addition to a four-year high school education is required for admission. The fees for the four years are, respectively, \$113, \$108, \$103 and \$125. The Dean is Dr. John O. McReynolds. Total registration for 1913-14 was 51; graduates, 17. The eleventh session begins Sept. 30, 1914, and ends June 3, 1915.

Fort Worth

TEXAS CHRISTIAN UNIVERSITY SCHOOL OF MEDICINE, Calloun and Fifth Streets.—Organized in 1894 as the Fort Worth School of Medicine, the Medical Department of the Fort Worth University. In 1912 the latter institution changed its name to Texas Christian University. The first class graduated in 1895. Became an integral part of Texas Christian University in 1913. It has a faculty of 19 professors and 38 lecturers, assistants, etc., in all 57. One year of collegiate work in addition to a four-year high school education is required for admission. The course covers four years of nine months each. The total fees for each of the four years, respectively, are \$114, \$113, \$108 and \$125. The Dean is Dr. I. C. Chase. The total registration for 1913-14 was 48; graduates, 11. The twenty-first session begins Sept. 8, 1914, and ends June 4, 1915.

Galveston

UNIVERSITY OF TEXAS DEPARTMENT OF MEDICINE, on the Strand, between Ninth and Tenth Streets.—Organized in 1891. The first class graduated in 1892. It has a faculty of 16 professors and 13 lecturers, a total of 29. The curriculum embraces four years of eight months each. The entrance requirement is one year of collegiate work in addition to a four-year high school education. The total fees for the four years, respectively, are \$75, \$50, \$27.50 and \$10. The Dean is Dr. William S. Carter. Total registration for 1913-14 was 172; graduates, 23. The twenty-fourth session begins Oct. 1, 1914, and ends May 31, 1915.

UTAH

Utah, population 373,351, has one medical college, the School of Medicine of the University of Utah, situated at Salt Lake City, which has 92,777 people.

To be eligible to secure licenses to practice medicine in Utah, students matriculating in and after the session of 1912-13, in addition to a four-year high school education, must have completed at least one year of collegiate work prior to beginning the study of medicine, this preliminary college work to have included college courses in physics, chemistry and biology.

Salt Lake City

UNIVERSITY OF UTAH SCHOOL OF MEDICINE.—Organized in 1906. Gives only first two years of the medical course. Each course covers thirty-six weeks. Two years of collegiate work are required for admission. The medical faculty consists of 10 professors and 9 lecturers and assistants, a total of 19. The fees are \$65 each year for residents and \$80 each year for non-residents. Total registration for 1913-14 was 20. The eighth session begins Sept. 14, 1914, and ends June 3, 1915.

VERMONT

Vermont, population 355,956, has one medical school, located at Burlington, a town of 20,468 people. Students matriculating in and after the session of 1912-13 who desire to practice medicine in Vermont, must have obtained a preliminary training of at least one year of collegiate work in addition to a standard four-year high school education, this additional year's work to include college courses in physics, chemistry and biology.

Burlington

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE, Pearl Street, College Park.—Organized with complete course in 1822. Classes graduated in 1823 to 1826, inclusive, when the school was suspended. It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years. The faculty numbers 48. One year of college

work in addition to a standard four-year high-school education is required for admission. The course of study covers four years of nine months each. The total fees for each of the first three years are \$145, and \$175 for the fourth year. The Dean is Dr. H. C. Tinkham. The total registration for 1913-14 was 117; graduates, 39. The next session begins Sept. 23, 1914, and ends June 23, 1915.

VIRGINIA

Virginia, population 2,061,612, has two medical colleges, one, the Department of Medicine of the University of Virginia, situated in Charlottesville, population 6,765, and the Medical College of Virginia at Richmond, population 127,628.

Only graduates of Medical Colleges registered by the Virginia State Board of Medical Examiners are eligible to obtain licenses to practice medicine in this state. Medical colleges to be so registered must require of all students admitted in the sessions of 1914-15 and thereafter, completion of at least one year of collegiate work including college courses in physics, chemistry and biology, in addition to a standard four-year high-school education.

Charlottesville

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. It has a faculty of 14 professors and 21 lecturers, instructors, assistants, etc., a total of 35. The requirements for admission are the completion of a four years' high school course, or its equivalent, and a year of college work devoted to chemistry, physics and biology. Total fees each year are \$140. The Dean is Dr. R. H. Whitehead. The total registration for 1913-14 was 104; graduates 17. The eighty-sixth session begins Sept. 14, 1914, and ends June 16, 1915.

Richmond

MEDICAL COLLEGE OF VIRGINIA, Marshall and College Streets.—Organized in 1838 as the Medical Department of Hampden Sydney College. Present title was taken in 1854. In 1913 the University College of Medicine was merged. Classes were graduated in 1840 and in all subsequent years. It has a faculty of 46 professors and 77 lecturers, instructors, etc., a total of 123. The requirement for admission is a four-year high school education and in addition a full year of collegiate work. The course embraces four years of eight months each. Fees, \$164 for the first year and \$114 for each subsequent year; graduation fee, \$30. The Dean is Dr. Stuart McGuire. The total registration for 1913-14, 386; graduates, 88. The eighty-sixth session begins Sept. 15, 1914, and ends June 1, 1915.

WEST VIRGINIA

West Virginia, population 1,221,119, has one medical college, the School of Medicine of West Virginia University, which offers the first two years of the medical course. It is located at Morgantown, a city of 9,150 population.

Morgantown

WEST VIRGINIA UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1902, and gives only the first two years of the medical course. One year of work in an approved college of liberal arts is required for admission. Session extend through nine months. The faculty numbers 11. Fees: For residents of the state, \$25 each year; for non-residents, \$50. The Dean is Dr. John N. Simpson. The total registration for 1913-14 was 21. The next session begins Sept. 14, 1914, and ends June 16, 1915.

WISCONSIN

Wisconsin, population 2,333,860, has two medical colleges, the Medical School of the University of Wisconsin, which teaches the first two years of the medical course, and is located at Madison, a city of 25,531 people, and the Marquette University School of Medicine, located at Milwaukee, a city of 373,857 people.

Madison

UNIVERSITY OF WISCONSIN MEDICAL SCHOOL.—Organized in 1907. Gives only the first two years of the medical course. For matriculation at least two years in a college of arts and science or an equivalent training are required, including two years of Latin, a reading knowledge of French and German, and at least a year's work in physics, chemistry and biology. It has a faculty of 11 professors and 14 lecturers, instructors, etc., a total of 25. Tuition fees: For residents of the state, \$70 each year; for non-residents, \$170. The Dean is Dr. Charles R. Bardeen. The registration for 1913-14 was 83. The seventh session begins Sept. 23, 1914, and ends June 18, 1915.

Milwaukee

MARQUETTE UNIVERSITY SCHOOL OF MEDICINE, Fourth Street and Reservoir Avenue.—Organized in December, 1912, by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. It has a faculty of 37 professors and 79 assistants, instructors, etc., a total of 116. The entrance requirements include, in addition to a four-year high school education, one year of college work, including courses in physics, chemistry, biology and a modern language. After Jan. 1, 1915, two years of college work will be required. The curriculum is for four years for thirty-four weeks each. The total fees for the four years, respectively, are \$180, \$175, \$175 and \$175. The Dean is Dr. Louis F. Jermain. The registration for 1913-14 was 169, graduates 43. The third session begins Oct. 1, 1914, and ends June 17, 1915.

PHILIPPINE ISLANDS

The Philippine Archipelago, having a population of 7,635,436, has two medical colleges, the University of the Philippines College of Medicine and Surgery and the Medical Faculty of the University of St. Thomas. They are located in the city of Manila, which in 1903 had a population of 219,928.

Manila

UNIVERSITY OF THE PHILIPPINES COLLEGE OF MEDICINE AND SURGERY, Manila.—Organized in 1907 as the Philippine Medical School, under the support of the government of the Philippine Islands. Present title in 1910. The faculty includes 22 professors and 44 lecturers, assistants, etc., a total of 66. Two years of collegiate work leading to the degree of Bachelor of Arts are required for admission. The course extends over five years of nine months each with an additional sixth year of intern service. The Dean is Dr. William E. Musgrave. The total registration for 1913-14 was 82, graduates 9. The eighth session begins July 1, 1914, and ends March 30, 1915.

CANADA

The Dominion of Canada has nine medical colleges, all but one of which require a five-year course, including in the first-year courses in physics, chemistry and biology. This course is practically equal to that in the colleges of the United States which require one year of college work for admission, including the science courses named. None of the Canadian colleges has a fixed minimum requirement of two years of collegiate work, or its equivalent, preliminary to or as a part of the medical course. A new medical school at Edmonton, Alberta gives only the first two years of the medical course, including the preliminary science year.

Alberta

UNIVERSITY OF ALBERTA, FACULTY OF MEDICINE, Edmonton.—Organized in 1913. Offers only the first two years of the medical course, including the preliminary science year. The faculty numbers 7. Fees for the first year are \$50; for the second, \$75. The registrar is Cecil E. Race, B.A. The registration for 1913-14 was 26. The second session begins Sept. 30, 1914, and ends May 12, 1915.

Manitoba

MANITOBA MEDICAL COLLEGE, Winnipeg.—It is the Medical Faculty of the University of Manitoba. Organized in 1883, first class graduated in 1886 and a class graduated each subsequent year. The faculty numbers 58. The fees are \$155 for the first year and \$150 for each subsequent year. The entire course covers five years, the first year including courses in physics, chemistry and biology. The Dean is Dr. H. H. Chown, 263 Broadway, Winnipeg. Total registration for 1913-14 was 188, graduates, 43. The next session begins Sept. 21, 1914, and ends May 1, 1915.

Nova Scotia

DALHOUSIE UNIVERSITY, FACULTY OF MEDICINE, Halifax, N. S.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the University. By an arrangement between Dalhousie University and the Provincial Medical Board of Nova Scotia, the final professional examinations are conducted conjointly by the University and the Board, and candidates may qualify at the same time for their academic degrees and the provincial license. First class graduated in 1872. It has a faculty of 37 professors, lecturers and demonstrators. Requires matriculation examination and a graded course of five years, including preliminary courses in physics, chemistry and biology. Fees are \$100 each year. Total registration for 1913-14 was 75, graduates, 15. The Secretary is Dr. A. W. H. Lindsay, 319 Pleasant Street, Halifax, N. S. The next session begins Sept. 9, 1914, and ends May 6, 1915.

Ontario

UNIVERSITY OF TORONTO, FACULTY OF MEDICINE, Toronto.—Organized in 1843 as the Medical Faculty of King's College. Abolished in 1853. Reestablished in 1887. In 1903 it absorbed Trinity Medical College. The course of study covers five years of eight months each, the first year including courses in physics, chemistry and biology. It has a faculty of 54 professors and 129 lecturers, associates, etc., a total of 183. The fees are \$150 each year. The Secretary is Dr. A. Primrose. The total registration for 1913-14 was 554, graduates, 85. The next session begins Sept. 29, 1914, and ends May 29, 1915.

QUEEN'S UNIVERSITY FACULTY OF MEDICINE, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty was originally a department of the University, but a separation took place in 1866, when the school was conducted under the charter of the Royal College of Physicians and Surgeons at Kingston. In 1892 the school again became an integral part of Queen's University. The faculty includes 25 professors and 14 assistants, instructors, etc., a total of 39. The fees amount to \$105 each year; fee for M.D., C.M. degrees, \$30. The course covers five years of seven months each, the first year including courses in physics, chemistry and biology. The total registration in 1913-14 was 268; graduates, 50. The Dean is Dr. J. C. Connell. The next session begins Sept. 14, 1914, and ends April 28, 1915.

WESTERN UNIVERSITY, FACULTY OF MEDICINE, London.—Organized in 1881, first class graduated in 1883 and a class graduated each year subsequently. The faculty numbers 37. The course is five years of eight months each, the first year including courses in physics, chemistry and biology. The tuition is \$110 each year. The Registrar is Dr. W. E. Vaughn. Total registration for 1913-14 was 90, graduates, 27. The next session begins Oct. 1, 1914, and ends June 5, 1915.

Montreal

MCGILL UNIVERSITY, FACULTY OF MEDICINE.—Founded 1824 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-39 owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop College. The course extends over five years of eight months each, including the preliminary year devoted to physics, chemistry and biology. The faculty numbers 120. The total fees are \$164 for each of the first four years and \$191 for the fifth. The total registration for 1913-14 was 382, graduates, 63. The Registrar is Dr. John W. Seane. The next session begins Oct. 1, 1914, and ends June 8, 1915.

MONTREAL SCHOOL OF MEDICINE AND SURGERY, Montreal.—Organized in 1878 as the Medical Department of Laval University. Present name assumed in 1911. First class graduated in 1879. The faculty numbers 60. The course extends over five years, including preliminary courses in physics, chemistry and biology. The Dean is Dr. E. P. Lachapelle. The total registration for 1913-14 was 132, graduates, 22. The next session begins Oct. 1, 1914, and ends June 20, 1915.

Quebec

LAVAL UNIVERSITY MEDICAL DEPARTMENT, Quebec.—The Quebec School of Medicine, organized in 1848, became in 1852 Medical Department of Laval University; first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 24. The fees are \$60 each year. The course extends over five years, the first year including courses in physics, chemistry and biology. The Dean is Dr. Michael Joseph Ahren, Quebec. Total registration for 1913-14 was 88, graduates, 14. The next session begins Sept. 9, 1914, and ends June 1, 1915.

STANDARDS OF THE COUNCIL ON MEDICAL EDUCATION OF THE AMERICAN MEDICAL ASSOCIATION

Essentials of an Acceptable Medical College

(Revised to August 10, 1914)

The following outline of the essentials of an acceptable medical college was issued by the Council on Medical Education of the American Medical Association for its suggestive value in the rapid development in progress among the medical colleges in the United States. It also represents the basis on which medical colleges are rated in the Council's classifications.

ADMISSION OF STUDENTS

1. A strict enforcement of the following standards and requirements, the college itself to be held responsible for any instances in which they are not enforced.

[Since the product of the medical school depends largely on the quality of the students admitted, in rating medical colleges, special emphasis is laid by the Council on the strictness and honesty by which the standards of admission and advanced standing are administered. By the admission of unfit students the school is handicapped from the very beginning and, in the opinion of the Council, deserves a low rating regardless of its equipment, its clinical facilities and its teaching force.]

2. A requirement for admission of at least a four-year-high-school education, and in addition at least one year of college work, including at least eight semester hours each of physics, chemistry and biology of college grade and a reading knowledge of German or French.

3. These minimum requirements for admission to the study of medicine are set forth in the following statements relating (1) to the high school work and (2) to the work of the preliminary college year. The prescribed minimum of work in physics, chemistry, biology and German or French should be required by every medical school whether given in a preliminary year by the medical school itself or required in one or more years of collegiate work. The statements are as follows:

ADMISSION TO THE PRELIMINARY COLLEGE YEAR

(a) For admission to the preliminary college year, students must have completed a four-year course of at least fourteen units in a standard accredited high school or other institution of standard secondary school grade, or have its equivalent as demonstrated by an examination. A transcript of the student's work should be secured direct from the principal of the secondary school by the college authorities and kept on file. This evidence of actual attendance at the secondary school or schools should be obtained for every student no matter whether he is admitted by examination or on presentation of acceptable credentials.

(b) The subjects for which credits for admission to the preliminary college year may be accepted are shown in the following schedule:

SCHEDULE OF SUBJECTS OFFERED IN ACADEMIC AND SECONDARY SCHOOLS, CREDITS IN WHICH ARE ACCEPTABLE FOR ENTRANCE TO THE PRELIMINARY COLLEGE YEAR LEADING TO THE MEDICAL COURSES

ENGLISH	SUBJECTS	UNITS	REQUIRED	ELECTIVE
	READING AND PRACTICE.....	2	2	
	Study and Practice.....	1	...	1
MATHEMATICS				
	ALGEBRA TO QUADRATICS.....	1	1	...
	Algebra (Quadratic Equations, Binomial Theorem and Progressions).....	1/2	...	1/2

Music		1	...	1
	Appreciation or Harmony.....	1	...	1
Total		35 1/2	7	28 1/2

A unit is the credit value of at least 36 weeks' work of 4 or 5 recitation periods per week, each recitation period to be of not less than 40 minutes. In other words, a unit represents a year's study in any subject in a secondary school constituting approximately a quarter of a full year's work. A satisfactory year's work in any subject cannot be accomplished under ordinary circumstances in less than 120 sixty-minute hours, or their equivalent.

Required Branches: Of the 14 units of high-school work it is suggested that the subjects in capitals aggregating 7 units be required. Other work to the amount of at least 7 units may be made up from any of the other subjects of the above schedule.

* Two units of Greek or Latin may be substituted for the two required units of French or German.

† Credentials of each science course should include evidence of laboratory work.

WORK OF THE PRELIMINARY COLLEGE YEAR

(c) The preliminary college year shall extend through one college session of at least thirty-two weeks of actual instruction, including final examinations.

(d) In excellence of teaching and in content, the work of this preliminary college year shall be at least equal to the work done in the freshman year in standard colleges and universities.

(e) This preliminary college year shall include courses in physics, chemistry, biology and German or French, each course to embrace at least eight semester hours of didactic and laboratory work in each subject as shown in the accompanying schedule, provided that a student may satisfy the requirement of physics in presenting one unit of high-school physics and completing a half year of college physics which continues and does not duplicate the work done in the high school.

(f) If a satisfactory "reading knowledge" of German or French is to be obtained in the one year of college work it is essential that an advanced course be offered and that the student have completed as a prerequisite in the high school two units of elementary work in German or French.

(g) By requiring two years of collegiate work for admission, medical schools would have a greater latitude in the acceptance of high-school credentials. For example, the language requirement in the high school would not be so essential since the deficiency could easily be made up in the two years of collegiate work.

(h) "College work" cannot be considered as acceptable unless it has been preceded by a completed course of study in a standard four-year secondary school or its full educational equivalent.

(i) Credits for two or more years of collegiate work cannot be considered acceptable unless courses in physics, chemistry and biology have been completed. It is urged that a reading knowledge of German or French also be required.

(j) Medical colleges giving these science courses in a premedical year, should provide expert full-time teachers in the various subjects, should provide laboratory equipment sufficient to enable the student to do the work intelligently and should provide a training in the subjects no less thorough than that given in standard colleges of liberal arts.

(k) Postgraduate courses given in high schools by high-school teachers cannot as a rule be considered equal to college courses given by college teachers.

SCHEDULE

Subject	Lectures or Recitations Per Week	Laboratory Periods* Per Week	Total Hours Per Semester	Total Semester Hours Per Year
Physics, 1....	2	2	4	8
Chemistry, 1..	2	2	4	8
Biology, 1....	2 or 3	2 or 1	4	8
German or French, 2...	4 or 3		4 or 3	8 or 6
Total	10	6 or 5	16 or 15	32 or 30

* Each laboratory period must extend over at least two hours.

OR, EXPRESSED IN CLASS HOURS

Subject	Total Hours Lectures, or Recitations	Total Hours Laboratory Work	Total Minimum Hours Didactic and Laboratory
Physics, 1....	64	128	192
Chemistry, 1..	64	128	192
Biology, 1....	64 or 96	128 or 64	192 or 160
German or French, 2..	128 or 96		128 or 96
Totals	320	384 or 320	704 or 640

(l) A year of work in a college of dentistry or a college of pharmacy should not as a rule be considered as an equivalent of the required premedical college science year.

(m) The object of the work of the preliminary college year is to provide the student with a training that will enable him to enter more readily and intelligently on the study of the fundamental medical sciences in the medical school.

4. Entrance Conditions. (a) During the next few years (until 1917) candidates who have completed at least one year of work in an approved college of liberal arts may be admitted conditioned in one-half of the required course in physics or one-half of the course in a modern language, these conditions to be removed before the beginning of the work of the second medical year.

(b) Candidates who have completed two or more years of work in an approved college of liberal arts may be admitted conditioned in all of the required course in physics or all of the course in a modern language, these conditions to be removed before the beginning of the second medical year.

(c) Candidates holding baccalaureate degrees from approved colleges of liberal arts but who have not taken the required courses in physics, chemistry or biology, may be admitted conditioned in those subjects, such conditions to be removed before entering on the work of the second medical year.

So far as possible, however, all deficiencies should be removed during the summer preceding entrance to the freshman medical year and the summer between the first and second medical years.

5. The college should require that students be in actual attendance in the college within the first week of each annual session and thereafter.

6. Actual attendance at classes should be insisted on except for good cause, such as for sickness, and under no circumstances should credit be given for any course where the attendance has been less than 80 per cent. of the full time.

7. (a) Full advanced standing may be granted to students only for work done in other acceptable colleges and in granting advanced standing there should be no discrimination against the college's full-course students. (b) In *exceptional cases* students from Class B medical schools may be given advanced standing but not higher than entrance to the third year (junior) class and no credit should be given in any subject except on the recommendation of the head of the department teaching that subject. (c) In *exceptional cases* students from Class C colleges may be given advanced standing but not higher than entrance to the second year (sophomore) class and then only after thorough examinations in all first year subjects have been passed.

SUPERVISION, EQUIPMENT, TEACHERS

8. There should be careful and intelligent supervision of the entire school by a dean or other executive officer who holds, and has sufficient authority to carry out fair ideals of medical education as interpreted by modern knowledge.

9. There should be a good system of records showing conveniently and in detail the credentials, attendance, grades and accounts of the students by means of which an exact knowledge can be obtained regarding each student's work. Records should also be kept showing readily the attendance of patients at the teaching hospitals and dispensaries; the maternity cases attended by students and the post-mortem cases used in teaching.

10. The college should have a fully graded course covering four years of at least 32 weeks each, exclusive of time required for matriculation and holidays, and at least 30 hours per week of actual work; this course should be clearly set forth in a carefully prepared and printed schedule of lectures and classes.

(a) The college should give two years of work consisting largely of laboratory work in thoroughly equipped laboratories in anatomy, histology, embryology, physiology, chemistry (inorganic, organic and physiologic), bacteriology, pathology, pharmacology, therapeutics and clinical diagnosis. Present day medical knowledge makes it quite essential that these subjects be in charge of full-time, thoroughly trained teachers.

(b) Two years of clinical work largely in hospitals and dispensaries, with thorough courses in internal medicine (including physical diagnosis, pediatrics, nervous and mental diseases), surgery (including surgical anatomy and operative surgery on the cadaver), obstetrics, gynecology, laryngology, rhinology, ophthalmology, otology, dermatology, hygiene and medical jurisprudence.

(c) As soon as conditions warrant, a fifth undergraduate year should be required which should be spent by the student as an intern in an approved hospital.

11. The college should provide at least six expert, thoroughly trained professors in the laboratory branches, salaried so that they may devote their entire time to instruction and to that research without which they cannot well keep up with the rapid progress being made in their subjects. These professors should have a definite responsibility in the conduct of the college, and their first and chief interest should be the training of medical students. It is advised that four of these professors be placed in charge of the departments of (a) anatomy, (b) physiology, (c) pathology and bacteriology and (d) physiologic chemistry and pharmacology. The other two may be assigned one to the laboratory course in histology and embryology under the department of anatomy and the other to the department

of pathology and bacteriology, possibly to the course in laboratory clinical diagnosis. There should also be a sufficient number of assistants in each department to look after the less important details. For colleges having sixty students or less in each class, there should be at least one full-time salaried assistant for each of the four departments mentioned, and at least one additional assistant in each of these departments should be provided for each additional thirty students enrolled. This represents a low average of the full-time assistants already employed by the accepted medical colleges.

12. The faculty should be thoroughly organized and should be made up of graduates of institutions recognized as medical colleges and who have had a training in all departments of medicine. Non-medical men should be selected as teachers in medical schools only under exceptional circumstances and only because medical men of equal special capacity are not available. All faculty members should be appointed because of their ability as teachers and not because they happen to be on the attending staff of a hospital or for other like reasons.

CLINICAL FACILITIES

13. The college should own or entirely control a hospital in order that students may come into close and extended contact with patients under the supervision of the attending staff. This hospital should be in close proximity to the college and have a daily average (for senior classes of 100 students or less) of not less than 200 patients which can be utilized for clinical teaching, these patients to be of such character as to permit the student to see and study the common variety of surgical and medical cases as well as a fair number in each of the so-called specialties.

14. The college should also have ample hospital facilities for children's diseases, contagious diseases and nervous and mental diseases.

15. At least six maternity cases should be provided for each senior student, who should have actual charge of these cases under the supervision of the attending physician. Careful records of each case should be handed in by the student.

16. Facilities should be provided for at least 30 necropsies during each college session which are attended and can be participated in by senior students (for senior classes of 100 students or less).

17. The college should own or control a dispensary, or outpatient department, the attendance to be a daily average of 60 cases (for senior classes of 100 students or less), the patients to be carefully classified, good histories and records of the patients to be kept and the material to be well used. The attending staff should be made up of good teachers, should be well organized and be regular in attendance.

OTHER TEACHING FACILITIES

18. The college should have a working medical library to include the more modern text and reference books with the *Index Medicus* and 30 or more leading medical periodicals; the library room should be properly lighted and heated, and easily accessible to students during all or the greater part of the day; it should be equipped with suitable tables and chairs, and have a librarian in charge.

19. A working medical museum having its various anatomic, embryologic, pathologic and other specimens carefully prepared, labeled and indexed so that any specimen may be easily found and employed for teaching purposes. It is suggested that so far as possible with each pathologic specimen coming from post-mortems there also be kept the record of the post-mortem, the clinical history of the patient on whom the necropsy was held and microscopic slides showing the equivalent structures of the disease shown in the gross specimen of the same.

The principal one should be sufficient dissecting material to enable and kept on an individually to dissect at least the lateral half secondary school cadaver; to provide cross-sections and other student no matter material and to allow of a thorough course for on presentation of a live surgery on the cadaver.

21. For modern experimental laboratory work in physiology, pharmacology and bacteriology as well as for a reasonable amount of medical research, a supply of animals—frogs, turtles, rabbits and guinea-pigs, if not also cats and dogs—is essential. Proper provision, also, is necessary for the housing and care of such animals. In any use made of animals great care should be used to prevent needless suffering and work by students should be carefully supervised.

22. A supply of such useful auxiliary apparatus as a stereopticon, a reflectoscope, carefully prepared charts, embryologic or other models, manikins, dummies for use in bandaging, a Roentgen ray and other apparatus now so generally used in medical teaching.

23. The college should show evidences of thorough organization and of reasonably modern methods in all departments and evidences that the equipment and facilities are being intelligently used in the training of medical students.

24. A clear statement of the college's requirements for admission, tuition, time of attendance on the classes, sessions, courses offered and graduation should be clearly set forth, together with complete classified lists of its matriculants and latest graduating class in regular annual catalogues or announcements.

By vote of the House of Delegates of the American Medical Association the Council on Medical Education has been given special instructions at various times as follows:

(a) Not to rate higher than Class C any medical college which gives the major portion of its instruction after four o'clock in the afternoon (Atlantic City, June, 1907).

(b) To include in Class A only such medical colleges as required for admission, in addition to an accredited four-year high school course, at least one year of college credits in physics, chemistry and biology (Atlantic City, June, 1912). In 1914 (June, Atlantic City), it was emphasized that the courses in physics, chemistry and biology to be acceptable should be of college grade.

(c) No college is to be rated higher than Class C which is conducted as a stock corporation in the interests of the stockholders. (Atlantic City, June, 1914.)

NOTE.—Correspondence from medical colleges regarding any of the above requirements is invited, and any further suggestions or information available will be gladly furnished.

Definitions of a Medical College* and a Medical School†

"An institution to be ranked as a medical college must have at least (6) professors giving their entire time to medical work, a graded course of four full years of college grade in medicine, and must require for admission not less than the usual four years of academic or high-school preparation, or its equivalent, in addition to the preacademic or grammar school studies."

By a medical school as differentiated from a medical college is meant a part of a university requiring for admission two years of collegiate work, or its equivalent, and offering instruction of not less than two years' duration, leading to the degree of Doctor of Medicine.

Grading of Medical Colleges

As in the previous classifications, all medical colleges were rated by the Council on Medical Education on a civil service basis on a scale of 1,000 points. The data relating to each college were grouped under ten general heads in such manner that the groups would have as nearly equal weight as possible, each group, allowing a possible 100 points (10 per cent.) out of a possible 1,000 points (100 per cent.). The ten heads under which the data were arranged are as follows:

1. Showing of graduates before state boards and other evidences of the training received.
2. Enforcement of a satisfactory preliminary educational requirement, granting of advanced standing and the character of records.
3. Character of curriculum, grading of course, length of session, time allowed for matriculation and supervision.
4. Medical school buildings; light, heat, ventilation, cleanliness.
5. Laboratory facilities and instruction.
6. Dispensary facilities and instruction.

* This definition of a college is based on that given in the revised ordinances of the state of New York. It has been adopted also by the Carnegie Foundation for the Advancement of Teaching.
† Based on the definition of the term "school" adopted in 1909 by the Association of American Universities.

7. Hospital facilities and instruction, maternity work, autopsies, specialties.
8. Faculty, number and qualifications of trained teachers, full-time instructors, and assistants, especially of the laboratory branches, organization, and extent of research work.
9. Extent to which the school is conducted for properly teaching the science of medicine rather than for the profit of the faculty directly or indirectly.
10. Possession and use made of libraries, museums, charts, stereopticons, etc.

Class A+ colleges are those which are acceptable; Class A those which need improvement in certain respects, but which are otherwise acceptable; Class B, those which, under their present organization, might be made acceptable by general improvements, and Class C, those which require a complete reorganization to make them acceptable.

Third Classification of Medical Colleges

Revised to June 21, 1914

CLASS A PLUS—ACCEPTABLE MEDICAL COLLEGES

1. Giving an Acceptable Four-Year Course:

CALIFORNIA

Leland Stanford Junior Univ., School of Med..San Francisco
University of California, College of Medicine.....
.....San Francisco-Los Angeles

CONNECTICUT

Yale Medical School.....New Haven

ILLINOIS

Northwestern University Med. School.....Chicago
Rush Medical College (University of Chicago).....Chicago

INDIANA

Indiana University School of Medicine.....
.....Bloomington-Indianapolis

IOWA

State Univ. of Iowa, Coll. of Med.....Iowa City

LOUISIANA

Tulane University of Louisiana, School of Med..New Orleans

MARYLAND

Johns Hopkins University, Medical Department...Baltimore

MASSACHUSETTS

Medical School of Harvard University.....Boston

MICHIGAN

University of Michigan, Dept. of Med. and Surg..Ann Arbor

MINNESOTA

University of Minnesota Medical School.....Minneapolis

MISSOURI

Washington University Medical School.....St. Louis

NEBRASKA

University of Nebraska, College of Medicine³..... Omaha

NEW YORK

Columbia University, College of Phys. and Surgs.....

.....New York City

Cornell University Medical College.....New York City

University and Bellevue Hospital Medical College.....

.....New York City

Syracuse University, College of Medicine.....Syracuse

OHIO

Medical College of the University of Cincinnati...Cincinnati

Ohio State University, College of Medicine³.....Columbus

Western Reserve University, School of Medicine...Cleveland

PENNSYLVANIA

Jefferson Medical College².....Philadelphia

University of Pennsylvania, School of Medicine.Philadelphia

University of Pittsburgh, School of Medicine²....Pittsburgh

TENNESSEE

Vanderbilt University, Medical Department¹.....Nashville

TEXAS

University of Texas, Department of Medicine.....Galveston

VIRGINIA

University of Virginia, Dept. of Med.....Charlottesville

2. Giving a Two-Year Course Acceptably:

MISSOURI

University of Missouri, School of Medicine.....Columbia

WISCONSIN

University of Wisconsin Medical School.....Madison

Total 29

CLASS A—COLLEGES ALSO ACCEPTABLE WHICH COULD MAKE CERTAIN IMPROVEMENTS TO ADVANTAGE

1. Giving a Complete Four-Year Course:

ALABAMA

University of Alabama, School of Medicine.....Mobile

COLORADO

University of Colorado, School of Med.....Boulder-Denver

DISTRICT OF COLUMBIA

Georgetown University, School of Medicine.....Washington

George Washington University, Med. School....Washington

Howard University, School of Medicine.....Washington

GEORGIA

Atlanta Medical College³.....Atlanta

University of Georgia, Medical Dept.⁴.....Augusta

ILLINOIS

University of Illinois, College of Medicine.....Chicago

IOWA

State Univ. of Iowa, Coll. of Homeopathic Med...Iowa City

KANSAS

University of Kansas, School of Med.....Lawrence-Rosedale

KENTUCKY

University of Louisville, Medical Department.....Louisville

MAINE

Medical School of Maine.....Brunswick-Portland

MARYLAND

College of Physicians and Surgeons.....Baltimore

University of Maryland, School of Medicine.....Baltimore

MASSACHUSETTS

Boston University School of Medicine.....Boston

Tufts College Medical School.....Boston

MICHIGAN

Detroit College of Medicine and Surgery⁵.....Detroit

University of Michigan, Homeopathic Med. Coll..Ann Arbor

MISSOURI

St. Louis University School of Medicine.....St. Louis

NEW YORK

Albany Medical College.....Albany

Fordham University, School of Medicine³....New York City

Long Island College Hospital⁵.....Brooklyn

New York Homeopathic Medical College and Flower

Hospital.....New York City

University of Buffalo, Medical Department.....Buffalo

OREGON

University of Oregon, Department of Medicine....Portland

PENNSYLVANIA

Hahnemann Medical College and Hospital.....Philadelphia

Medico-Chirurgical College of Philadelphia.....Philadelphia

Woman's Medical College of Pennsylvania.....Philadelphia

1. Rating changed to Class A+ June 21, 1914.

2. Rating changed to Class A+ Feb. 24, 1914.

3. Rating changed to Class A Feb. 24, 1914.

4. Rating changed to Class A Feb. 24, 1913.

5. Rating changed to Class A June 21, 1914.

TENNESSEE

University of Tennessee, College of Medicine⁶.....Memphis

VERMONT

University of Vermont, College of Medicine.....Burlington

VIRGINIA

Medical College of Virginia.....Richmond

2. Giving a Two-Year Course:

MISSISSIPPI

University of Mississippi, Department of Medicine...Oxford

NEW HAMPSHIRE

Dartmouth Medical School.....Hanover

NORTH CAROLINA

University of North Carolina, School of Medicine..Chapel Hill

Wake Forest College, School of Medicine.....Wake Forest

NORTH DAKOTA

University of North Dakota, School of Medicine..University

SOUTH DAKOTA

University of South Dakota, College of Medicine...Vermilion

UTAH

University of Utah, School of Medicine.....Salt Lake City

Total 38

CLASS B—COLLEGES NEEDING GENERAL
IMPROVEMENTS TO BE MADE
ACCEPTABLE

1. Giving a Complete Four-Year Course:

ALABAMA

Birmingham Medical College⁶.....Birmingham

ARKANSAS

University of Arkansas, Medical Department.....Little Rock

CALIFORNIA

College of Physicians and Surgeons.....Los Angeles

Hahnemann Medical College of the Pacific....San Francisco

Oakland College of Medicine and Surgery.....Oakland

ILLINOIS

Bennett Medical College.....Chicago

Chicago College of Medicine and Surgery.....Chicago

Hahnemann Medical College and Hospital.....Chicago

NEBRASKA

John A. Creighton Medical College.....Omaha

NORTH CAROLINA

North Carolina Medical College⁷.....Charlotte

OHIO

Eclectic Medical College.....Cincinnati

OKLAHOMA

Univ. of Oklahoma, School of Med..Norman-Oklahoma City

PENNSYLVANIA

Temple University, Department of Medicine....Philadelphia

SOUTH CAROLINA

Medical College of the State of South Carolina⁸....Charleston

TENNESSEE

Lincoln Memorial University, Medical Dept.⁹.....Knoxville

Meharry Medical College¹⁰.....Nashville

6. Will offer only a postgraduate course after the class of 1915 has graduated.
7. Has merged with the Medical College of Virginia at Richmond, but will retain a nominal existence until it has granted the degrees for the three remaining classes which will receive the balance of their medical instruction at Richmond. Rating changed to Class B June 21, 1914.
8. Rating changed to Class B Feb. 24, 1913.
9. Has merged with the University of Tennessee, College of Medicine at Memphis. The three remaining classes will be taught at Memphis, but the degrees will be granted by the Lincoln Memorial University. Rating changed to Class B June 21, 1914.
10. Rating changed to Class B Feb. 24, 1914.

TEXAS

Baylor University, College of Medicine.....Dallas

Texas Christian University, School of Medicine¹¹.Fort Worth

Southern Methodist University, Medical Dept.¹¹.....Dallas

WISCONSIN

Marquette University, School of Medicine.....Milwaukee

2. Giving a Two-Year Course:

NORTH CAROLINA

Leonard Medical School¹².....Raleigh

WEST VIRGINIA

West Virginia University School of Medicine...Morgantown

Total 22

CLASS C—COLLEGES REQUIRING A COMPLETE
REORGANIZATION TO MAKE THEM
ACCEPTABLE

CALIFORNIA

California Eclectic Medical College.....Los Angeles

College of Physicians and Surgeons.....San Francisco

College of Medical Evangelists.....Loma Linda

GEORGIA

Georgia College of Eclectic Medicine and Surgery....Atlanta

Southern College of Med. and Surgery¹³.....Atlanta

ILLINOIS

Chicago Hospital College of Medicine.....Chicago

Jenner Medical College.....Chicago

MARYLAND

Eastern University School of Medicine¹⁴.....Baltimore

Maryland Medical College¹¹.....Baltimore

MASSACHUSETTS

College of Physicians and Surgeons¹⁵.....Boston

MISSOURI

American Medical College.....St. Louis

Eclectic Medical University¹⁶.....Kansas City

Ensworth Medical College.....St. Joseph

Kansas City Hahnemann Medical College.....Kansas City

St. Louis College of Physicians and Surgeons.....St. Louis

NEBRASKA

Cotner University Medical College.....Lincoln

NEW YORK

New York Med. Coll. and Hosp. for Women..New York City

OHIO

Cleveland-Pulte Medical College.....Cleveland

Toledo Medical College.....Toledo

TENNESSEE

University of West Tenn. Coll. of Med. and Surg...Memphis

Total 20

Note.—Official statements from the following state licensing boards indicate that as a rule the colleges rated in Class C are not recognized:

Alabama	Maryland (Reg.)	Pennsylvania
Arkansas (Reg.)	Michigan	Porto Rico
Colorado	Minnesota	Rhode Island
Connecticut (Reg.)	Mississippi	South Carolina
Delaware	New Hampshire	South Dakota
Florida	New Jersey	Texas
Georgia	New Mexico	Vermont
Indiana	New York	Virginia
Iowa	North Dakota	West Virginia
Kentucky	Ohio	Wisconsin
Louisiana (Reg.)	Oklahoma	

Of the above states the boards of New Hampshire, Rhode Island and Virginia recognize only the medical colleges listed in Classes A+ and A.

11. Rating changed to Class B May 10, 1914.
12. Has discontinued clinical teaching, hereafter to give only two years of the medical course. Rating changed to Class B June 21, 1914.
13. Reported not recognized by the Georgia State Board of Medical Examiners.
14. Reported not recognized by the Maryland State Board of Medical Examiners.
15. Reported not recognized by the Massachusetts Medical Society.
16. Reported not recognized by the Missouri State Board of Health.

State Requirements of Higher Preliminary Education

There are now twenty states which have adopted requirements of preliminary education in addition to a standard four-year high-school education. These states, the number of college years required and the time the higher requirement becomes effective are as follows:

State Examining Board of—	Number of Years Required	Affects Students Matriculating	Affects All Applicants
Minnesota	2	1908-09	1912
North Dakota	2	1908-09	1912
Colorado	2	1910-11	1914
Connecticut	1	1910-11	1914
Kansas	2	1910-11	1914
Indiana	1	1910-11	1914
Utah	1	1910-11	1914
Iowa	2	1911-12	1915
South Dakota	2	1911-12	1915
Vermont	1	1912-13	1916
Illinois	1	1914-15	1918
Kentucky	1	1914-15	1918
Michigan	1	1914-15	1918
New Hampshire	1	1914-15	1918
Pennsylvania	1	1914-15	1918
Rhode Island	1	1914-15	1918
Virginia	1	1914-15	1918
Alabama	2	1915-16	1919
Arkansas	1	1915-16	1919
California	1	1915-16	1919

Colleges Having Higher Entrance Requirements

The thirty-four medical schools which are now requiring as a minimum for entrance *two or more years* of work in a college of liberal arts in addition to a four-year high-school education are as follows:

	Requirement Began
CALIFORNIA	
Leland Stanford Junior University, School of Medicine.....	1909
University of California, College of Medicine.....	1905
COLORADO	
University of Colorado, School of Medicine	1910
CONNECTICUT	
Yale Medical School	1909
DISTRICT OF COLUMBIA	
Georgetown University, School of Medicine.....	1912
Howard University, School of Medicine	1914
ILLINOIS	
Northwestern University Medical School	1911
Rush Medical College (University of Chicago)	1904
University of Illinois, College of Medicine	1914
INDIANA	
Indiana University, School of Medicine	1910
IOWA	
State University of Iowa, College of Medicine.....	1910
State University of Iowa, Coll. of Homeopathic Medicine.....	1910
KANSAS	
University of Kansas, School of Medicine.....	1909
MARYLAND	
Johns Hopkins University, Medical Department.....	1893
MASSACHUSETTS	
Medical School of Harvard University	1900
MICHIGAN	
University of Michigan, Department of Medicine and Surgery....	1909
MINNESOTA	
University of Minnesota Medical School	1907
MISSOURI	
University of Missouri, School of Medicine.....	1910
Washington University Medical School	1912
NEBRASKA	
University of Nebraska, College of Medicine	1909
NEW HAMPSHIRE	
Dartmouth Medical School	1910
NEW YORK	
Columbia University, College of Physicians and Surgeons.....	1910
Cornell University Medical College.....	1908
Syracuse University, College of Medicine.....	1910
NORTH CAROLINA	
Leonard Medical School	1914
Wake Forest College School of Medicine.....	1908
NORTH DAKOTA	
University of North Dakota, School of Medicine	1907

OHIO

Western Reserve University School of Medicine.....	1901
Medical College of the University of Cincinnati.....	1913

PENNSYLVANIA

University of Pennsylvania, School of Medicine.....	1910
University of Pittsburgh, School of Medicine.....	1913

SOUTH DAKOTA

University of South Dakota, College of Medicine.....	1909
--	------

UTAH

University of Utah, School of Medicine.....	1910
---	------

WISCONSIN

University of Wisconsin Medical School	1907
--	------

The fifty following colleges require, in addition to a four-year high-school course, one year of college work in physics, chemistry, biology and a modern language, the requirement beginning in the year given:

ALABAMA

In Force

University of Alabama, School of Medicine	1914
---	------

CALIFORNIA

College of Physicians and Surgeons, Los Angeles.....	1914
College of Medical Evangelists	1914

DISTRICT OF COLUMBIA

George Washington University, Medical School.....	1914
---	------

GEORGIA

Atlanta Medical College	1914
University of Georgia, Medical Department.....	1914

ILLINOIS

Bennett Medical College	1914
Chicago College of Medicine and Surgery.....	1914
Hahnemann Medical College and Hospital	1914
Jenner Medical College	1913

KENTUCKY

University of Louisville, Medical Department.....	1914
---	------

LOUISIANA

Tulane University of Louisiana, School of Medicine.....	1910
---	------

MAINE

Medical School of Maine	1912
-------------------------------	------

MARYLAND

College of Physicians and Surgeons.....	1914
University of Maryland, School of Medicine	1914

MASSACHUSETTS

Boston University, School of Medicine	1914
Tufts College Medical School	1914

MICHIGAN

Detroit College of Medicine and Surgery	1914
University of Michigan, Homeopathic Medical College.....	1912

MISSISSIPPI

University of Mississippi, Department of Medicine	1914
---	------

MISSOURI

St. Louis University, School of Medicine	1910
American Medical College	1914

NEBRASKA

John A. Creighton Medical College	1914
---	------

NEW YORK

Albany Medical College	1914
Fordham University, School of Medicine	1911
Long Island College Hospital	1914
University and Bellevue Hospital Medical College.....	1912
University of Buffalo, Medical Department	1914

NORTH CAROLINA

University of North Carolina, School of Medicine	1910
--	------

OHIO

Ohio State University, College of Medicine.....	1914

* From the Third Classification of Medical Colleges, revised to June 21, 1914. See page 669.

REFERENCES

- After the one remaining class has been graduated, this college will discontinue undergraduate medical teaching.
- Gives a five-year course, including a number of theoretical, non-medical, subjects.
- It is rumored that this college has been suspended.
- Reported closed following withdrawal of recognition by the Georgia State Board of Medical Examiners.
- No tuition fees charged by this college for students who are bona fide residents of Georgia.
- Catalogue contains names of 238 "matriculants and applicants," including dental students. The number of medical students actually in attendance is approximately as given.
- Fees given are for non-residents; they are \$10 less each year for residents of Michigan.

(h) These colleges give only the work of the first two years of the medical course.

(i) This college has been closed.

(j) No information obtained as to whether this college will reopen or not.

(k) This college has been merged with the Medical College of Virginia at Richmond.

(l) Reported to have transferred its property to the Ohio State University.

(m) This college was formerly the Starling-Ohio Medical College.

(n) Reported closed following withdrawal of recognition by the Ohio State Medical Board.

(o) This medical school will admit women students hereafter.

(p) This college has merged with the University of Tennessee College of Medicine at Memphis.

(q) This medical school is controlled and financed by the government. No tuition fees are charged.

(r) Gives only the work of the first two years of the Canadian five-year course, which corresponds to the preliminary college science year, and the first medical year in the United States.

(s) All these colleges give a five-year course, which includes a year of preliminary science work. This is the equivalent of the course given by the fifty medical schools in the United States which require one year of college preliminary science work for entrance. The course is surpassed by thirty-four medical colleges in the United States which require two years of collegiate work for admission.

VIRGINIA

Medical College of Virginia	1914
University of Virginia, Department of Medicine.....	1910

WEST VIRGINIA

West Virginia University, School of Medicine	1911
--	------

WISCONSIN

Marquette University, School of Medicine	1914
--	------

The five following medical colleges shown in the above list as now requiring one year of collegiate work for admission have announced that all students admitted in the session of 1915-16 and thereafter will be required to have completed two years of such collegiate work.

University of Alabama, School of Medicine.
Ohio State University, College of Medicine.
Woman's Medical College of Pennsylvania.
Medical College of Virginia.
Marquette University, School of Medicine.

The Medical Department of the University of Arkansas and the Hahnemann Medical College of the Pacific announce that all students admitted in 1915-16 will be required to present at least one year of collegiate work or enter on a five-year course including a preliminary year of college physics, chemistry and biology.

Hospital Intern Year

Three medical colleges have adopted the requirement of a fifth year to be spent by the student as an intern in an approved hospital or in other acceptable clinical work before the M.D. degree will be granted. These colleges and the sessions when the requirement became effective are as follows:

University of Minnesota, Medical School.....	1910-11
Leland Stanford Jr. University, School of Medicine.....	1914-15
Rush Medical College.....	1914-15

One state licensing board, that of Pennsylvania, now requires that every candidate to be eligible for license to practice medicine in that state, must have served at least one year as an intern in an approved hospital. The requirement became effective in 1914.

Graduate Courses in Public Health

Graduate courses in public health have been established in connection with seven medical schools leading to a degree of Doctor of Public Health (Dr.P.H.), Certified Sanitarian (C.S.), Master of Science in Public Health (M.S.(P.H.)) or Master of Public Health (M.P.H.). The course is for one year except at the Universities of Michigan, Minnesota and Wisconsin where the course for the Doctorate covers two years. Wisconsin gives a Diploma in Public Health (D.P.H.) for a one-year course. These colleges are as follows:

MEDICAL COLLEGES GIVING COURSES IN PUBLIC HEALTH

Name of College	Course started in	Degree granted	Years in Course	Degrees required for entrance	Fees

* For residents of Michigan the fees for the one- and the two-year courses, respectively are \$62 and \$104. † For residents of Wisconsin the fees are \$70 less each year. ‡ Information not obtained.

State University Medical Schools

Twenty-eight states now have medical schools as integral parts of the state universities or—in one instance—under state control as separate institutions. These states and other interesting data regarding the medical schools are as follows:

STATE UNIVERSITY MEDICAL SCHOOLS

Medical School of State University of	Only School in State	Length of Med. Course in Years.	Years of College Work for Admission.	Medical School of State University of	Only School in State	Length of Med. Course in Years.	Years of College Work for Admission.

* Have Homeopathic Departments.

1. To require 1 year in 1915

2. To require 2 years in 1915.

3. Similar requirements by Licensing Board.

In fifteen states no other medical schools exist, medical education in the state being entirely in charge of the state university. This will be true in Alabama also in 1915, when an independent medical school now existing will give only post-graduate instruction.

Of the twenty-eight state medical schools, twenty give the complete medical course and grant M.D. degrees while eight give only the first two years of the medical course. Minnesota requires a five-year course, the fifth year to be spent by the student in a hospital as an intern, or in other recognized clinical work. The universities of Iowa and Michigan have Homeopathic departments and one is contemplated also in Ohio. In Iowa the entrance requirements are the same for the two departments, but in Michigan, while for the regular department two years of collegiate work are required for entrance, only one year is required for the Homeopathic College; nevertheless, the students of the two colleges are taught together in the work of the first two years.

As may be noted, fourteen of these state university medical schools are now requiring for admission two years of collegiate work. The medical schools of the University of Alabama and the Ohio State University have announced the two-year requirement to take effect in 1915. As already shown the state schools are supported in this requirement by the state licensing boards in Colorado, Indiana, Iowa, Minnesota, North Dakota and South Dakota. This will be true also in Alabama in 1915. Of the twelve remaining state university medical schools all but the University of Arkansas are now requiring for admission a standard four-year high-school course and in addition one year of collegiate work. The one year requirement becomes effective in Arkansas also in 1915 both for the Medical School and the State Licensing Board.

The Combined Course in Liberal Arts and Medicine

There are fifty-six medical schools which announce that arrangements have been made whereby students can secure degrees in both arts and medicine in six or seven years' time. Many have arranged for the B.S. and M.D. degrees in six years, or the A.B. and M.D. degrees in seven years. Nine of these colleges give only the first two years of the medical course and, therefore, offer only the first four or five years of the combined course. These are indicated by the figures four and five in parentheses. The list of medical schools follows:

* This college requires a five-year course in medicine and theology, and the combined arts-medical-theological course is seven years.

† Two years in college and five years in medicine are required for the B.S. and M.D. degrees, three years in college and five years in medicine for the A.B. and M.D. degrees. The five-year medical course includes the hospital intern year.

The Association of American Medical Colleges

The requirements for admission to and graduation from colleges holding membership in this association are as follows:

SECTION 1.—Every college holding membership in this Association shall, on and after Jan. 1, 1912, require for matriculation a completed or unconditioned medical student's certificate, to be granted by a state medical examining and licensing board, or a board empowered by statute to grant such certificates, or a certificate of entrance to the academic department of any state university, or a certificate of entrance to an accredited university or college, providing that said certificate is granted on no less than the following requirements:

(a) A bachelor's degree from an accredited college or university.

(b) A diploma and transcript of record from a fully accredited high school, normal school or academy requiring for admission evidence of the completion of a standard course in primary and intermediate grades, and for graduation, the completion of a standard four-year high-school course, embracing two years (2 units) of mathematics, two years (2 units) of English, two years (2 units) of one foreign language, one year (1 unit) of American history and civics, and seven years (7 units) of further credit in language, literature, history or science, making the total of units at least fourteen; and in addition, one year each of physics, chemistry and biology of college grade of each not less than eight semester hours.

(c) An examination in the following branches totaling 14 units:

(A) Required, 7 units.	Units
Mathematics (minimum 2 years, maximum 3 years), algebra and plane geometry.....	2
English (minimum 2 years, maximum 4 years).....	2
One foreign language (minimum 2 years, maximum 4 years).....	2
History (U. S.) and civics.....	1
Total number of required units.....	7

(B) Elective, 7 units.

To be selected from the following:

	Units
English language and literature (in addition to the required work).....	1 to 2
Foreign languages, additional, Latin, German, Italian, French, Spanish or Greek (not less than 1 year in any one).....	1 to 4
Advanced mathematics, advanced algebra, solid geometry and trigonometry (½ year each).....	1
Natural science, chemistry 1 year, physics 1 year, and biology, botany, physiology and zoology (½ to 1 year each).....	½ to 2
Earth science, physical geography, geology and agriculture (½ year to 1 year each).....	½ to 1
Astronomy (½ year).....	½
Drawing (½ to 1 year).....	½ to 1
History, ancient, medieval and modern, and English (1 year each).....	1 to 3
Economics (½ year).....	½
Manual training (1 year).....	1
Book-keeping (½ to 1 year).....	½ to 1

And in addition one year each of physics, chemistry and biology of college grade, of each not less than 8 semester hours.

One unit in any subject is the equivalent of work in that subject for four or five periods per week for a year of at least thirty-six weeks, periods to be not less than forty-five minutes in length. One unit is equivalent to 2 semester credits or 2 points.

THE PRELIMINARY COLLEGE YEAR

(a) The preliminary college year shall extend through one college session of at least thirty-two weeks of actual instruction, including final examinations.

(b) In excellence of teaching and in content, the work of this preliminary college year shall be equal to the work done in the freshmen year in standard colleges and universities.

(c) This preliminary college year shall include courses in physics, chemistry, biology and German or French, each course to embrace at least eight semester hours of didactic and laboratory work in each subject as shown in the following schedule, provided that a student may satisfy the requirement of physics in presenting one unit of high-school physics and completing a half year of college physics which continues physics and does not duplicate the work done in the high school; provided also that a student may satisfy the requirement of French or German by presenting two units of regular high-school work in either language and completing a half year of college work in that language, which con-

tinues and does not duplicate the work done in the high school, or by presenting three units of regular high-school work in French or German.

In the administration of the entrance requirements of the preliminary college year by the members of this Association conditions may be allowed until September, 1917, amounting to not more than one-half of the requirement in physics and one-half of the requirement in a modern language.

All such conditions shall be removed before registration for the second year.

SCHEDULE

Subject	Lectures or Recitations Per Week	Laboratory Periods* Per Week	Total Hours Per Semester	Total Semester Hours Per Year
Physics, 1..	2	2	4	8
Chemistry, 1	2	2	4	8

(d) In medical colleges planning to give the work of the preliminary year, provision should be made for full-time expert teachers in the various subjects. Sufficient equipment should be provided to enable the students to do the work intelligently—in amount such as will compare favorably with the equipment for these courses in standard colleges and universities.

(e) It should be remembered that the chief object of the work of the preliminary college year is to provide the student with a training that will enable him to enter more readily and intelligently on the study of the fundamental medical sciences in the medical school.

Sec. 2.—The examination of credentials must be conducted by and under the authority of the board of medical examiners of the state in which the college is located, or by a duly authorized examiner of the college entrance examination board, or the authorized examiner of an accredited university, state or otherwise, or by an examiner whose certificates are accepted by accredited colleges or universities, or by a method approved by the judicial council of this association.

Sec. 3.—The term "accredited" as applied to high schools, academies, colleges and universities means institutions of that type that have been investigated and are accredited by the state university of their respective states, by the North Central Association of Colleges and Secondary Schools, the Association of Colleges and Preparatory Schools of the Southern States, the Association of Colleges and Preparatory Schools of the Middle States and Maryland, the New England College Entrance Certificate Board, the Association of American Universities and the Association of State Universities, provided that such accrediting is based on Article III, Section 1, of this constitution.

Sec. 4.—Colleges in membership in this Association may honor the official credentials presented by students from other colleges having the standard requirements maintained by members of this Association, excepting for the fourth year of the course, but no member of this Association shall admit a student to advanced standard without receiving from the dean, secretary or registrar of such college a direct written communication certifying to the applicant's standing. Credit for time or scholarship cannot be given beyond that of the college issuing the credentials, except by mutual agreement between the colleges.

Sec. 5.—Candidates for the degree of Doctor of Medicine shall have attended four courses of study in four calendar years, each annual course to have been of not less than thirty-two teaching weeks' duration, and at least ten months shall intervene between the beginning of any course and the beginning of the preceding course.

Sec. 6.—No time credit shall be given to holders of a Bachelor's degree, but subject credit may be given on satisfactory examination. Four years of residence in a medical college shall be required of all candidates for the degree of Doctor of Medicine.

Sec. 7.—A college which gives less than a four years' course of study, but does not graduate students, and is possessed of other required qualifications, may be admitted to membership.

Sec. 8.—Each student shall be obliged to attend not less than 80 per cent. of the exercises in every annual course of study for which he seeks credit. No student shall be given credit on examination unless he attains a grade of at least 70 per cent. or its equivalent in any other marking system. And no student shall be graduated unless he shall have attained a passing grade in each and all subjects of the required curriculum.

CURRICULUM

SECTION 1.—The entire course of four years shall consist of at least 4,000 hours for each student, and shall be grouped in divisions and subdivided into subjects; each division and subject to be allotted the number of hours as shown in the following schedule:

DIVISION 1.—ANATOMY, 720 Hours (18 per Cent.)

	Hours.	Lect.	Rec.	Dem.	Lab.	Wk.
(a) Gross anatomy (including applied anatomy)	510				120	390
(b) Histologic and microscopic anatomy	135				30	105
(c) Embryology	75				30	45

DIVISION 2.—PHYSIOLOGY AND CHEMISTRY, 600 Hours (15 Per Cent.)

	Hours.	Lect.	Rec.	Dem.	Lab.	Wk.
(a) Inorganic chemistry	180				60	120
(b) Organic chemistry	75				30	45
(c) Physiologic chemistry	104				30	75
(d) Physiology	240				140	100

DIVISION 3.—PATHOLOGY, BACTERIOLOGY AND HYGIENE, 450 Hours (11.25 Per Cent.)

	Hours.	Lect.	Rec.	Dem.	Lab.	Wk.
(a) Bacteriology	135				30	105
(b) Hygiene and general dietetics	45				45	
(c) Pathology	270				60	210

DIVISION 4.—PHARMACOLOGY, MATERIA MEDICA AND THERAPEUTICS, 240 Hours (6 Per Cent.)

	Hours.	Lect.	Rec.	Dem.	Lab.	Wk.
(a) Pharmacology	105				40	65
(b) Materia medica and pharmacology	80					
(c) Therapeutics	55					

DIVISION 5.—MEDICINE AND MEDICAL SPECIALTIES, 970 Hours (24.25 Per Cent.)

	Hours.	Lect.	Rec.	Dem.	Lab.	Wk.
(a) General medicine (including clinical microscopy)	640					
(b) Pediatrics	150					
(c) Nervous and mental diseases	105					
(d) Jurisprudence, ethics and economics	30					
(e) Dermatology and syphilis	45					

TABLE 3.—MEDICAL STUDENTS SHOWN BY CLASSES

* Figures are approximate. † There were 262 students in the first two years.

Note.—This table gives for each college, from which the information was obtainable, the number of students enrolled in each of the four classes. Some colleges do not publish classified lists of their students. Nine colleges teach only the work of the first two years. Birmingham Medical College taught only juniors and seniors and the Ensworth Medical College of St. Joseph, Mo., taught only seniors.

This table is very interesting in the light of the rapid trend toward higher entrance requirements and should be studied in connection with the lists of colleges given on pages 671 and 675. Some of the colleges holding to higher standards show an increase in their first year enrollments, thereby recovering from the reductions which immediately followed the adoption of the higher standards. Such increases are shown for Yale Medical School, Rush Medical College, University of Kansas School of Medicine, University of Michigan Department of Medicine and Surgery and the University of Minnesota Medical School.

In numerous instances a larger freshman class shows a college which has continued to hold to a high school education or lower standards for entrance while the majority of medical colleges have voluntarily raised their requirements for admission to one or two years of collegiate work. Among such colleges which have increased freshman classes are: College of Physicians and Surgeons, Los Angeles; George Washington University Medical School; Jenner Medical College; University of Louisville Medical Department; Tufts College Medical School; University of Buffalo Medical Department; Ohio State University College of Medicine; Medico-Chirurgical College, Philadelphia; Vanderbilt University Medical Department and the Medical College of Virginia. Smaller freshman classes will be the rule for these colleges next session, however, since practically all of them hereafter require at least one year of collegiate work for admission in addition to a high school education.

The actual enforcement of higher preliminary standards always results in a decreased enrollment. Atlanta Medical College vigorously enforced a high school educational requirement and reduced its entering class by almost half. That the University of Illinois College of Medicine and Marquette University School of Medicine enforced for the first time the preliminary requirement of one year of collegiate work is evidenced by the smaller freshman classes enrolled.

The six colleges having the largest enrollments are Jefferson Medical College, 648; Chicago College of Medicine and Surgery, 633; Atlanta Medical College, 483; Rush Medical College, 462; University of Maryland School of Medicine, 454, and the University of Illinois College of Medicine, 422. There are twenty-eight medical colleges each of which has over 200 students enrolled.

DIVISION 6.—SURGERY AND SURGICAL SPECIALTIES, 720 Hours

(18 Per Cent.)	Hours.	Lect.	Rec.	Dem.	Lab.	Wk.
(a) General surgery	510	...	...	...	...	...
(b) Orthopedic surgery	45	...	...	...	...	...
(c) Genito-urinary diseases	45	...	...	...	...	...
(d) Eye	60	...	...	...	...	...
(e) Ear, nose and throat.....	60	...	...	...	...	...

DIVISION 7.—OBSTETRICS AND GYNECOLOGY, 300 Hours

(7.5 Per Cent.)	Hours.	Lect.	Rec.	Dem.	Lab.	Wk.
(a) Obstetrics	195	...	...	...	...	...
(b) Gynecology (including some abdominal surgery)	105	...	...	...	...	...

Colleges may reduce the number of hours in any subject not more than 20 per cent. provided that the total number of hours in a division is not reduced. Where the teaching conditions in a college are best subserved, the subject may be, for teaching purposes, transferred from one division to another. When didactic and laboratory hours are specified in any subject, laboratory hours may be substituted for didactic hours.

SEC. 2.—Each medical college in membership in the Association shall print in every annual catalogue or announcement a table of the total number of hours work given in said college, arranged both by subjects and years.

SEC. 3.—Each college in membership in this Association shall print annually a list of its students by classes.

COLLEGE NOTES

Colleges Closed During the Year.—Six medical colleges have been reported as closed during the year, of which two were closed by merger into other colleges. The colleges are:

Georgia College of Eclectic Medicine and Surgery, Atlanta.
 Southern College of Medicine and Surgery, Atlanta, Ga. This college was closed, it is reported, following withdrawal of recognition by the Georgia State Board of Medical Examiners.

Ensworth Medical College, St. Joseph, Mo. This college graduated its last class and voluntarily closed.

North Carolina Medical College, Charlotte, N. C. This college was merged with the Medical College of Virginia at Richmond.

Toledo Medical College, Medical Department of the Toledo University. Reported closed following withdrawal of recognition by the Ohio State Medical Board.

Lincoln Memorial University, Medical Department, Knoxville, Tenn. Merged with the University of Tennessee, College of Medicine at Memphis.

Special Items Concerning Medical Education

Alabama.—The University of Alabama School of Medicine will require two years of collegiate work for admission beginning with the session of 1915-16.

—The Alabama State Board of Medical Examiners has adopted two years of collegiate work as the minimum standard of preliminary education which will apply to all candidates matriculating in the session of 1915-16 and thereafter who desire to secure licenses to practice medicine in Alabama. It affects all graduates of 1919 and thereafter.

California.—The Leland Stanford Junior University, School of Medicine, received a gift of \$10,000 by the will of Charles G. Latrop.

—A sum of \$615,750 was obtained from various donors by the University of California Medical Department and used for building a new teaching hospital.

Colorado.—The faculty of the University of Colorado, School of Medicine, has undergone a complete reorganization. In place of the medical senate there is now an executive committee of five members, including the dean as chairman. Three standing committees on curriculum, hospitals and dispensary have been appointed, the chairman of each being a member of the executive committee.

Connecticut.—Yale Medical School has received \$500,000 from the General Education Board (the Rockefeller Foundation), on condition that the school procure complete control of the New Haven General Hospital and that the professors in the main clinical branches be placed on the full-time or university basis.

—Yale Medical School has also received a gift of \$400,000 by the will of the late Mrs. George Lauder to establish a chair of public health.

Georgia.—The Georgia legislature appropriated \$30,000 for the Medical Department of the University of Georgia for maintenance for two years.

Illinois.—Beginning with the session of 1914-15 all matriculants in medical colleges who expect to secure licenses in Illinois must have completed at least one year in a college of liberal arts before entering on the study of medicine or have its full equivalent in a medical school giving the five-year course.

—The alumni of Rush Medical College have raised \$10,000 toward a sum of \$30,000 to be added to the endowment fund of their Alma Mater. This college has limited its enrolment to 100 students in each of the first and second years and 120 students in each of the third and fourth years.

—A sum of \$1,000,000 has been donated by Mr. James Deering to Wesley Hospital of Chicago to be used as an endowment fund for charity beds. It is provided that Wesley Hospital be a teaching hospital with a staff made up from the faculty of the Northwestern University Medical School.

Indiana.—The Robert W. Long State Hospital at Indianapolis, the teaching hospital of the University of Indiana School of Medicine, has been completed at a total cost of \$225,000, which was the gift of Dr. and Mrs. Robert W. Long. The University of Indiana has also received a gift of 160 acres of Texas land, the proceeds from the sale of which will go toward the maintenance of the Long Hospital.

Maryland.—The General Education Board (the Rockefeller Foundation) has given to the Medical Department of Johns Hopkins University a gift of \$1,500,000 in order that the professors of the three main clinical departments might be placed on a full-time or academic basis. Another gift of \$50,000 from the same source was obtained, to be used in the developing of the Hunterian laboratories.

—Another gift of \$250,000 was received by Johns Hopkins University, Medical Department, from James Buchanan Brady for a urological clinic which will be known as the Brady Urological Clinic. Mr. Brady's gift also provides for \$15,000 annually for maintenance.

—The Johns Hopkins University, Medical Department, has limited its enrolment to 90 students in each class.

—The endowment funds being raised for the University of Maryland School of Medicine, by its alumni, amounted in the last report to \$31,633, of which about one-third is for the pathological endowment fund and two-thirds for the faculty of physic fund. The university is making an effort also to secure some endowed scholarships.

Massachusetts.—Harvard University is to receive "a greater part" of an estate of \$500,000—exact amount not stated—to be used for medical research.

—The Peter Bent Brigham Hospital at Boston has been completed at a cost, including the land and the erection of the buildings, of \$1,350,000. The grounds immediately adjoin the campus of the Medical School of Harvard University. This hospital has remaining a fund of \$4,500,000 to provide an income for maintenance.

Michigan.—Detroit College of Medicine and Surgery is reported to have raised \$100,000 toward a \$1,000,000 endowment fund.

Minnesota.—The University of Minnesota Medical School has established teaching fellowships in the clinical departments, with a view of providing well-trained, full-time assistants and research workers and at the same time give a basis for graduate instruction in the specialties. The fellowships are in three grades: first year, \$500; second year, \$750, and third year, \$1,000.

—The University of Minnesota, Medical School, has provided a graduate course of two years for the training of specialists in ophthalmology, and opportunity will be provided so that courses in otology, laryngology and rhinology may be taken at the same time. A suitable degree will be granted at the end of the course.

Missouri.—Washington University Medical School received a gift of \$150,000 by the will of Adolphus Busch. From the General Education Board \$750,000 was received on condition that, from other sources, the sum be increased to \$1,500,000, and that it be used to place the professors of the main clinical chairs on a full-time or academic basis.

—The new group of buildings for the Washington University Medical School, the Barnes Hospital and the St. Louis Children's Hospital have been completed on the new campus at Kingshighway and Euclid Avenue, St. Louis. The total cost exceeds \$1,000,000. There is also a fund of \$2,000,000, the income from which provides for the maintenance of the Barnes Hospital.

Nebraska.—The University of Nebraska, College of Medicine, has moved into its new building on the Omaha campus, and now all four years of the medical course are given in Omaha. The new building was erected at a cost of \$115,000.

New York.—A closer affiliation has been established between the Columbia University, College of Physicians and Surgeons and the Presbyterian Hospital which gives to the former larger teaching privileges.

—Columbia University received \$200,000 from the family of the late W. Bayard Cutting for traveling fellowships open to graduates of the university, including the medical school. Other gifts were \$2,500 for surgical research and \$1,000 for salaries in the department of physiology.

—The Long Island College Hospital received \$20,000 by the will of Mrs. Matilda E. Webb.

—Under the will of the late Dr. Roswell Park, his entire library consisting of about three thousand volumes was given to the University of Buffalo, Medical Department.

—The New York Homeopathic Medical College and Flower Hospital has received a donation of \$25,000 for research work in cancer.

—The University and Bellevue Hospital Medical College received a gift of \$10,000 by the will of the late Dr. Joseph D. Bryant to provide for a more thorough teaching of medical ethics.

—Albany Medical College received a gift of \$5,000 by the will of Sylvester McDonald. Another gift of \$10,000 was received by the will of Dr. John M. Bigelow.

—Cornell University, Medical College, received as an endowment \$4,000,000 from (it is believed) Col. Oliver Hazard Paine of New York City. This is perhaps the largest individual gift ever made to a medical school. The gift provides an annual income of about \$200,000.

—The endowment of the Rockefeller Institute for Medical Research has been increased by its founder by \$2,500,000. An additional \$1,000,000 was given to establish a department of animal pathology. The total gifts by Mr. Rockefeller to the institute now amounts to \$12,500,000. Mr. James J. Hill gave \$50,000 to the new department of animal pathology to use in the study of hog cholera. Dr. Theobald Smith, formerly professor of comparative pathology at the Medical School of Harvard University, has been made director of this new department.

Ohio.—The Medical College of the University of Cincinnati has received from the will of Mrs. Francis W. Gibson the sum of \$31,400 to go toward the endowment fund. A gift of \$25,000 was received by the will of Mrs. Jeanette Moss to endow the chair of medicine.

Oregon.—A site for the University of Oregon, Department of Medicine, valued at \$100,000 has been donated by the Oregon-Washington Railroad and Navigation Company, with the stipulation that the site be occupied by a hospital or by institutions for the furtherance of scientific research and teaching.

Pennsylvania.—The Woman's Medical College of Pennsylvania has received \$22,500 toward a \$500,000 endowment fund. An appropriation of \$10,000 was made by the Pennsylvania legislature for the Hospital of the Woman's Medical College of Pennsylvania.

—Jefferson Medical College has purchased for \$12,000 a three-story brick building adjoining the Baugh (Jefferson College) Institute of Anatomy.

—The University of Pennsylvania School of Medicine has received gifts as follows: \$15,000 to endow three beds in the children's orthopedic ward of the University Hospital; a residuary fund of \$1,500,000 for the University library, the University Hospital, and the departments of dermatology, archeology and paleontology. The faculty has voted to admit women students beginning this fall.

—The University of Pittsburgh School of Medicine has received as a gift the library of the late Prof. Ernest Zeisler, for many years professor of pathology at the University of Freiburg, which was purchased for the University by Mr. Richard Beatty Mellen. In addition to the above Mr. Mellen has endowed a fellowship in internal medicine and also provided funds to install and maintain an electrocardiographic apparatus.

—A scholarship amounting to \$12,000 for the benefit of women students has been provided at the University of Pittsburgh School of Medicine by a congress of the women's clubs of western Pennsylvania.

Tennessee.—Vanderbilt University, Medical Department, has been made secure in its rights to use the \$1,000,000 given last year by Mr. Andrew Carnegie. This was brought about by the supreme court decision that the Board of Trustees of Vanderbilt University and not the General Conference of the Methodist Episcopal Church had the right to fill vacancies on that board.

Total Gifts During the Year.—During the last twelve months, so far as reports indicate, the total gifts for new laboratories and medical-school buildings was approximately, \$567,500; for endowments and maintenance, \$8,163,500; for research and public health instruction in medical schools, \$675,000, a total of \$9,406,000. If to this is added the \$4,010,750 given to build and maintain teaching hospitals and the \$3,550,000 given for medical research at the Rockefeller Institute, the grand total of donations for medical education, teaching hospital and research during the year would be \$16,966,750. This does not include the regular incomes of the medical schools for maintenance coming through the regular university channels.

Another School of Public Health

The University of Minnesota inaugurates, with the fall session, a school of public health to be administered by the medical school, through a committee in direct charge. The ranking member of its faculty will sit in the administrative board of the medical school.

It will begin with the offer of courses for medical health officers. These courses have been laid out for the ensuing year. The doctorate in medicine will be a preliminary requirement. The first year's work may, however, be taken by post seniors of the medical school in lieu of the required year of hospital internship. A certificate of proficiency in sanitary science will be given on the satisfactory completion of the first year's work. This will be followed, however, by advanced courses, for a second year, leading to a degree, probably, in public health.

The first year's curriculum will call for a total of 1,000 hours, of which 500 will be devoted to required work and 500 to elective work.

The required courses will deal with public health laws; public health organization and administration; the theory and practice of statistics; personal hygiene; school hygiene; infant mortality; the sanitation of travel; industrial hygiene; communicable diseases; sex hygiene and venereal diseases; the hygiene of milk; of water supplies and of food; sewerage; refuse collection and disposal; the sanitation of buildings; town planning; housing; labor problems; economic conditions in American cities; school supervision; general physiography; elements of psychology; municipal administration, and hospital administration.

Among the electives provided are courses in epidemiology, public health laboratories, Pasteur institute, sanitary engineering, water and sewage laboratory methods, school hygiene, vital statistics, physical and human geography, protozoology, algae, meteorology, construction and interpretation of geologic maps, infant mortality, mental retardation, experimental psychology, dairy chemistry, study of meats, and animal parasites and parasitic diseases.

The school of public health will also plan and conduct courses in sanitary and hygienic subjects in other departments of university instruction.

It will have general oversight of the health interests of the university communities and will frame sanitary regulations for the benefit of students and faculties.

MEDICAL EDUCATION IN THE UNITED STATES

The tabulated statistics herewith presented (page 657) are for the year ending June 30, 1914, and are based on reports received from the medical colleges or from other reliable sources. We take pleasure in acknowledging here the courtesy and cooperation of the various officials who have made the compilation of these complete statistics possible.

STATISTICS OF COLLEGES

Table 1 (pages 674-676) gives the colleges in session during 1913-1914; the population of the city; the rating given to the college in the third classification of the Council on Medical Education; the number of students, men and women, registered during the year; the number of 1914 graduates, men and women; the number of graduates holding collegiate degrees; the number of teachers for each college; the number of weeks of actual work in the college year; the total fees for each year; the executive officer of the college, and the dates of beginning and ending of the next session. The figures in heavy-faced type show the totals by states. Beginning on page 657 are given essential facts concerning all medical colleges arranged by states.

NUMBER OF MEDICAL STUDENTS

The total number of medical students (matriculants) in the United States for the year ending June 30, 1914, excluding premedical, special and postgraduate students, was 16,502, a decrease of 513 below last year, a decrease of 1,910 below 1912 and a decrease of 11,640 below 1904, when 28,142, the highest number of students, were enrolled. Of the total number

1914.....	15,438	794	270	...	...	16,502

of students, 15,438 were in attendance at the non-sectarian (regular) colleges, 794 at the homeopathic and 270 at the eclectic colleges. The attendance at the non-sectarian colleges shows a decrease of 481 below that of last year, a decrease of 1,839 below 1912 and a decrease of 9,492 (38 per cent.) below 1903, when 24,930, the largest number of non-sectarian students, were enrolled. In the homeopathic colleges there was a decrease of 55 below the attendance of last year, a decrease of 31 below 1912 and a decrease of 1,105 (58 per cent.) below 1900, when 1,909, the largest

number of homeopathic students, were enrolled. The eclectic colleges show an increase of 14 over the registration of last year but a decrease of 38 below 1912 and a decrease of 744 (73 per cent.) below 1904, when the largest number of eclectic students were enrolled.

NUMBER OF MEDICAL GRADUATES

The total number of graduates for the year ending June 30, 1914, was 3,594, a decrease of 387 below 1913, and a decrease of 889 below 1912. The total this year is 2,153 (37.5 per cent.) less than in 1904, when 5,747, the largest number, were graduated. The

TABLE 5.—MEDICAL COLLEGE GRADUATES

1907.....	4,591	225	121	11	32	4,980
1908.....	4,370	215	116	12	28	4,741
1909.....	4,163	209	84	15	44	4,515
1910.....	4,113	183	114	16	14	4,440
1911.....	4,006	162	110	5	..	4,273
1912.....	4,206	185	92	..	..	4,483
1913.....	3,679	209	93	..	..	3,981
1914.....	3,370	154	70	..	..	3,594

number of graduates from the non-sectarian colleges was 3,365, or 314 less than last year, and 841 less than in 1912. It is a decrease of 1,825 (35 per cent.) below 1904, when 5,190, the largest number, were graduated from non-sectarian colleges. From the homeopathic colleges there were 154 graduates, or 55 less than in 1913, and 31 less than in 1912. It is a decrease of 266 (63 per cent.) below 1903, when 420, the largest number of homeopathic physicians, were graduated. The eclectic colleges graduated 70, or 23 less than last year, and 40 less than in 1911. It is a decrease of 151 (68.3 per cent.) below 1890, when 221, the largest number of eclectic physicians, were graduated.

GRADUATES HOLDING DEGREES IN ARTS

Of the 3,594 medical graduates, 807, or 22.5 per cent., were reported to hold also degrees in arts or science, as compared with 18.9 per cent. last year, 17 per cent. in 1912, 16.5 per cent. in 1911 and 15.3 per cent. in 1910. Of the 3,365 non-sectarian school graduates, 794, or 23.5 per cent., were reported to have baccalaureate degrees, while of the homeopathic graduates, 7, or 4.5 per cent., were so reported, and of the eclectic graduates, 6, or 8.6 per cent., were reported as holding degrees from colleges of liberal arts. As will be noted by referring to Table 14, of the 807 graduates holding baccalaureate degrees, 127—the largest number—came from Illinois colleges, followed by 97 from New York, 90 from Maryland, 79 from Pennsylvania and 70 from Massachusetts. It is noted that, as expected, the percentage of graduates holding collegiate degrees is gradually increasing and will con-

tinue to increase, particularly in the non-sectarian colleges, because a larger number of medical schools are requiring college work for admission.

WOMEN IN MEDICINE

During the past year there were 631 women studying medicine, or 9 less than last year, a decrease of 48 below 1912 and a decrease of 498 (44.1 per cent.) below 1904, when 1,129 women students, the largest number, were reported. The percentage of all medical students was 3.8, the same as last year. There were 121 women graduates this year, or 3.4 per cent. of all graduates. Of all the women matriculants, 135 (21.4 per cent.) were in attendance at the two medical colleges for women, while the remaining 496 (78.6 per cent.) were matriculated in the 54 coeducational colleges. From the two women's colleges there were 25, or 20.7 per cent. of all women graduates, while 96, or 79.3 per cent., secured their degrees from coeducational colleges.

NUMBER OF COLLEGES

Until last year no exact data were available on which absolute statements could be made regarding the number of medical schools existing in the various years prior to 1900. Through the work of the Council on Medical Education, however, sufficient reliable data regarding all medical schools were collected and the chart prepared which was published last year,¹ from which the actual number of schools existing in any one year could be positively stated. Table 8 allows

of comparisons between the number of colleges existing in recent years.

Since June 30, 1913, six colleges (mentioned on page 681) have suspended or merged with others, leaving 101 medical colleges still existing. The number of colleges is the smallest number since 1880. It was about that time that the movement toward establishing commercial medical colleges became most marked, and the rapid increase in the number of colleges has been paralleled only by the rapid decrease since 1904. There has been a net decrease of sixty-one colleges since 1906, when there were 162 and when this country had about one-half of the world's supply of medical colleges! Eighty-five colleges have been closed by merger or otherwise since 1904, but in the same time twenty-four new colleges were organized, leaving 101 medical colleges which still exist.

The non-sectarian (regular) colleges number 87, a decrease of 5 since last year. The homeopathic colleges number 10, the same as last year and the eclectic

TABLE 8.—MEDICAL COLLEGES

1913.....	92	10	5	..	..	107
1914.....	87	10	4	..	..	101

tic colleges number 4, a decrease of 1 since last year. The non-sectarian colleges show a net reduction of 43, or 33.1 per cent., since 1906, when there were 130, the largest number of non-sectarian medical colleges. The homeopathic colleges show a net decrease of 12, or 54.5 per cent., since 1901, when 22, the largest number of homeopathic colleges, were in existence. The eclectic colleges show a net reduction of 6, or 60 per cent., since 1901, when there existed 10, the largest number of eclectic colleges.

FEWER BUT BETTER COLLEGES

Of the eighty-five medical colleges which have ceased to exist since 1904, forty-nine were closed by merger and thirty-five became extinct. It is noteworthy that this rapid diminution in the number of colleges began with the creation of the Council on Medical Education in 1905. The largest numbers closing in single years were ten in 1907, when the Council's first classification of medical colleges was prepared, thirteen in 1910, when the second classification was published, and fourteen in 1913, when the third classification was made public.

1. Life Chart of the Medical Colleges in the United States, THE JOURNAL A. M. A., Aug. 23, 1913, p. 578.

It is interesting to note that of the eighty-five medical colleges which have been closed, 44 were rated by the Council on Medical Education in Classes A and B and 41 in Class C. It is also interesting to note that 41, or 93 per cent. of the closures of the medical colleges in Classes A and B were through merger with other colleges, while of the Class C colleges which

* Based on the classifications of medical colleges prepared by the Council on Medical Education.

closed only six, or less than 15 per cent., were through merger with other colleges. In fact, all but three of the colleges which became extinct had been rated in Class C by the Council on Medical Education.

While the total number of colleges is growing smaller, however, and *approaching more nearly the normal supply for this country*, it is encouraging to note that the number of high-grade, stronger medical colleges is constantly increasing. In 1904 only four medical colleges were requiring any preliminary education in advance of the usual high-school education;

now there are eighty-four² requiring one or more years of advance college work and several others which begin the higher requirement next year. Of these eighty-four colleges, there are thirty-four which are requiring two years or more of collegiate work for admission. Many of the colleges have been remarkably improved also in regard to buildings, new laboratories, better equipment, larger hospital facilities and—most important—more and better full-time, salaried instructors.

FURTHER MERGERS NEEDED

There are still eighteen cities each of which has two or more medical schools, and in seven of these mergers

are scarcely possible, owing to the fact that the schools differ as to sect or race, leaving eleven cities where mergers are still possible. These cities and the number of colleges in each are as follows: Chicago, 8; New York, 7; Philadelphia, 6; Boston, 4; San Francisco, 4; St. Louis, 4; Baltimore, 3; Los Angeles, 3; Washington, 3; Dallas, 2, and Omaha, 2. In 1904 there were twenty-four cities having each from two to eight non-sectarian medical schools.

Each of the most famous medical centers in Europe—for example, Berlin, Paris, Vienna—has but one large medical school which makes systematic and practical use of the clinical facilities of the respective city. There is no valid reason why this country should not have equally famous medical centers, but the highest development is prevented by the existence of too many competing medical schools. For the further improve-

ment not only of undergraduate but also of postgraduate medical instruction in this country, there should be other mergers in the eleven cities named.

LENGTH OF TERMS

The length of term of each college fluctuates somewhat from year to year, but on the whole, during the last twelve years there has been a decided lengthening of college terms. This has reference to the weeks of actual work exclusive of holidays. Only two colleges this year reported sessions shorter than twenty-nine weeks, whereas in 1901, one hundred colleges reported sessions of from twenty-three to twenty-eight weeks. Four colleges claim courses of twenty-nine or thirty weeks of actual work, twenty-five claim courses of thirty-one or thirty-two weeks, and forty-one, the largest number, claim courses of from thirty-three to thirty-four weeks. Of the 101 colleges now existing, 94, or 94.1 per cent., now claim to require from thirty-one to thirty-six weeks of actual work, exclusive of holidays, as compared with 91.5 per cent. in 1913, 85 per cent. in 1912, 76 per cent. in 1910, 42 per cent. in 1904 and only 30 per cent. in 1901. The one college claiming a course of thirty-seven weeks is a night school, but it would require twelve or fourteen years of the usual night school study to obtain the equiva-

lent of four years of thirty-two weeks each in one of the better day colleges.

TUITION AND OTHER FEES

Special attention is called in Table 1 on Page 672 to the total amount charged by the various colleges per annum for tuition, matriculation, laboratory and graduation fees for each student. In Table 13 the 101 remaining colleges have been grouped according to the amount of fees charged and according to their classification by the Council on Medical Education in Classes A, B and C. Fourteen colleges charge fees of \$100 or less per year, sixty-six between \$100 and \$175, and twenty-one charge above \$175. Of the fourteen colleges charging \$100 or less, eight, or nearly two-thirds, were listed among Class A (acceptable) colleges³ by the Council on Medical Education, three were in Class B and three of them are found among the Class C colleges. Among the eight Class A colleges having these low fees are the schools of medicine of the state universities of Colorado, Mississippi, Missouri, North Dakota, South Dakota, Texas and Utah. On the other hand, eleven colleges listed by the Council in Class C charge fees of from \$100 to \$175 per year for each student. As shown on page 670, diplomas from Class C colleges are reported as not recognized by thirty-one state licensing boards. It is a question, therefore, why a student should spend his time and money in a low-grade college the diplomas of which are not recognized in many states,⁴ when in the same time and with even less money he can attend one of the best-equipped colleges, the diplomas of which are recognized in all states. Although thirty-seven colleges listed in Class A charge fees ranging from \$150 to \$275 per year for each student, the actual expense for teaching that student in these colleges amounts to from two or three, to several times these sums. In fact, accurate data secured from sixty-five medical colleges a few years ago showed that the average amount received each year from the individual student was \$122, while the average amount actually expended in the training of that student for

a year was \$410! The excesses of cost over income per student in several schools were, respectively, \$2,744, \$1,863, \$897, \$747, \$730, \$673, \$518 and \$500. The excess of expense over income from fees per student was over \$200 in twenty-eight of the medical colleges which reported. It is also clearly evident that with the same equipment and at practically no additional expense these schools could easily accommodate

* Based on the latest classification of medical colleges prepared by the Council on Medical Education.

two, three, or in some instances several times the number of students at present enrolled, which would greatly reduce the disproportion of expense over income from fees. A further reduction in the vast oversupply of medical schools in this country, therefore, would be in the interests of economy as well as of marked advantage to medical education.

COLLEGES, STUDENTS AND GRADUATES BY STATES

Illinois has heretofore had the largest number of medical colleges, but now, as shown in Table 14, the first place is held by New York, where there are ten colleges. California and Illinois each has eight and Missouri and Pennsylvania each has seven colleges. Illinois still has the largest number of students enrolled, having 2,474 matriculants last session, followed by New York with 2,153, Pennsylvania with 1,675 and Tennessee with 1,209. In regard to the graduates, the same relative position obtains.

Table 15 shows the colleges existing during the last session and their students and graduates grouped according to their rank in the third classification of the Council on Medical Education. As will be noted, there were sixty-eight colleges in Classes A+ and A and 20 each in Classes B and C. It is encouraging to note that 74.7 per cent. of all students are enrolled in the 63 per cent. of colleges which are in Classes A+ and A, and that these colleges turn out 73 per cent. of all graduates. At the other extreme, only 8.1 per cent. of all students and 7 per cent. of all graduates are from the 18.5 per cent. of colleges rated in Class C.

HOME STATES OF MEDICAL STUDENTS

Table 2, on 676 to 679, shows from what states the students come who were in attendance at each medical college during the session of 1913-1914. The influence of the proximity of the medical school is seen in the fact that states having medical colleges contribute

3. See list on page 669.
4. See also in THE JOURNAL of May 23, 1914, p. 1650, the table showing in what states the diplomas of the various medical colleges are not given full recognition.

more students in proportion to the population than those which have no colleges. This is shown by the dark zone of figures running diagonally down the page. A comparison of this table with the large tables based in state board examinations,⁵ which show the distribution of the alumni of each college, is interesting. The college which has widely distributed alumni usually has a student body from an equally large number of states.

The state furnishing the largest number of students this year was New York, with 2,100. Pennsylvania contributed 1,341 and Illinois 1,258. The next states, in the order of the number of students contributed, are: Ohio, 791; Massachusetts, 701; Georgia, 598; Texas, 573; Missouri, 528, and Tennessee 499. Four states had less than 20 each, these being Arizona, 16, Wyoming, 11; New Mexico, 7 and Nevada, 3. There were 126 students from Hawaii, Porto Rico and the Philippine Islands, and 555 students from foreign countries.

In Table 3, on page 680, the students enrolled in each college are shown by classes. This permits one to see whether the attendance at each college is increasing or decreasing. The total attendance for the first year in all colleges is larger than that of the second year by 703. More interesting, however, is the study of this table in the light of higher entrance requirements which have been adopted during the last two or three years by a large number of colleges.⁶ The effects of

these higher requirements are shown in the figures in two ways: smaller enrolments for the colleges which have adopted the higher requirements and larger enrolments for the colleges which have retained the lower requirements. The benefit in larger classes for the "stand pat" colleges can be only temporary, however, so decided is the trend for the higher standards. Already twenty state licensing boards have gone on record for the higher requirements and others are contemplating similar action. The House of Delegates of the American Medical Association in June, 1912, adopted a report instructing the Council on Medical Education to omit from the acceptable list any medical college which after Jan. 1, 1914, does not require for admission in addition to the four-year high-school education, at least one year of higher preliminary work, including courses of college grade in physics, chemistry and biology. The Association of American Medical Colleges has adopted a similar requirement. The medical profession in the United States, therefore, has gone on record for entrance qualifications

TABLE 15.—STATISTICS ACCORDING TO COLLEGE CLASSIFICATION

which bring medical education in this country more nearly on a par with the requirements of other countries.

RELATIONS WITH BETTER HOSPITALS

Another great wave of improvement, already well begun, is the establishing of closer relationships between hospitals and medical schools, whereby each of the hospitals will have on its attending staff the most skilled physicians who are engaged in teaching and research, and the medical school will possess a teaching hospital in which students may see and study patients at the bedside. This closer relationship is a direct acknowledgment on the part of the hospital that the medical school has improved to such an extent that it is a real honor and a benefit to have a closer relationship with it. This closer relationship undoubtedly means that the hospitals will be conducted along more modern lines since on their attending staffs they will have physicians who are in touch with the latest improved methods of diagnosis and treatment. This relationship means that medical students will be given a better training in the examination and care of patients and that—most important—the public will in future be supplied with better qualified physicians.

DIETARY TREATMENT AND THE SUGAR CONTENT OF THE BLOOD IN DIABETES

The significance of the sugar-content of the blood in the diagnosis and prognosis of certain disturbances, notably diabetes mellitus, is beginning to be recognized. Data are rapidly accumulating from which it will soon be possible to formulate standards and variations which may be taken as indicative of fairly definite perversions of function. The influence of the ingestion of various kinds of carbohydrates on the level of sugar concentration in the blood has been clearly established, as has the fact that the blood-sugar content of the diabetic departs from the normal both with respect to the existence of a hyperglycemia and in its unlike response to altered alimentary conditions.¹

If there is any aspect of the subject respecting which the records furnished by the new mode of investigation are not yet as complete as might be desired, it is in connection with the influence of the routine dietary treatment of diabetes on the hyperglycemia. Extensive statistics in this field can be obtained only from the larger hospitals and sanatoriums in which suitable patients and adequate laboratory facilities are available. A series of cases studied with reference to some of the features here emphasized has just been reported from the Rudolf Virchow-Krankenhaus in Berlin.² The introduction of a carbohydrate-free regimen consistently produced a decrease in the sugar content of the blood in such cases as were not complicated with chronic nephritis. The extent of the diminution corresponded in general with the severity of the disease. Cases of the mildest type of diabetes were brought to a sugar level characteristic of the normal in perfect health. Moderately severe cases under the same dietary regulations reached a definite level of the blood-sugar which was as a rule higher than the normal, fluctuated with the severity of the symptoms, and was

rather unresponsive to further rigorous treatment. Patients in this class usually reacted to the feeding of carbohydrate more intensely in the direction of increased hyperglycemia than did those exhibiting a less severe diabetes. No variations from these general rules were brought about by such complicating factors as tuberculosis of the lungs, cirrhosis of the liver, or arteriosclerosis.

It is a significant and perhaps unexpected fact that when the lower level of blood-sugar, whatever its figure, characteristic of each case, was once reached, further restrictions in the diet produced no additional lowering of the glycemia. Even after a diminution in the protein intake, as on the days on which green vegetables formed the chief ingredient of the diet, thus approaching a partial starvation level, no reduction of the sugar content was manifested in the blood, although the glycosuria sometimes disappeared at this time. Herein the analysis of the blood reveals a picture not afforded by the examination of the urine alone. It is also worthy of note that on the "oatmeal days," the blood-sugar was, if anything, increased in the cases investigated.

In cases that ended by death in coma the patients showed an increased hyperglycemia, even though they were fasting prior to the examination. In such conditions it seems necessary to assume severe disturbances in intermediary metabolism. The symptoms in nephritic persons were also divergent in some cases. Although in suitable instances the urine frequently became free from sugar after the customary diet restrictions, the sugar-content of the blood was invariably above normal. In some cases, for example, those with contracted kidneys, the hyperglycemia increased even when the glycosuria had permanently disappeared. It is evident, therefore, that such studies on the blood serve as a valuable supplement to other current methods of routine examination. They may furnish evidence of a latent defect of metabolism when it no longer manifests itself by way of more familiar methods.

A RARE ANIMAL PARASITE OF MAN

The extension of medical research into the field of the tropics has brought many novelties and rarities into prominence. One of these is a variety of parasites which infest either man or animals or both. The parasitic invaders of the blood-stream have received most attention, in part because the blood is easily made available for examination. Interest is at present especially centered on the alimentary parasites; and increased necropsies in those countries where the unusual organisms are likely to be revealed have resulted in considerable progress in knowledge. The value of a systematic and thorough study of every branch of parasitology does not consist solely of the possibility of eradicating objectionable causes of dis-

1. The Variation in the Content of Sugar in the Blood, editorial, THE JOURNAL A. M. A., Jan. 10, 1914, p. 131; Adrenal Glycosuria in Man, *ibid.*, March 21, 1914, p. 938.
2. Wolf, L., and G. Mann, S.: In welcher Weise wirken Diätikuren auf das Verhalten des Blutzuckers bei Diabetikern? *Ztschr. f. klin. Med.*, 1914, lxxix, 394.

ease or of relieving the distress produced by some of the undesired invaders of the body. The study of the life-history of even the most uncommon and unimportant of these forms of animal existence may throw light on related harmful species and through the information gained give us more effective means of avoiding or combating parasitic infections. For this reason any advance in the field of parasitology should awaken interest quite aside from the immediate promise of useful application. We sometimes need to recall how few years have elapsed since the suspicion arose of the interrelation of insects and disease.

One of the rarities of tropical medicine, namely, oesophagostomiasis, a disease attributable to a parasitic worm of the genus *Oesophagostoma*, was first described by Brumpt in 1905, in a negro from the Omo River near Lake Randolph, East Africa. According to the very few reports of cases, the malady is characterized by features somewhat akin to hookworm. Hemorrhagic cysts or tumors in the submucosa or muscularis of the large intestine—rarely of the small intestine—usually project both inside and outside of the canal, and contain the immature adult oesophagostoma. At maturity the cyst ruptures and the adult worm escapes into the lumen of the intestine. The ruptured cysts may be invaded by intestinal bacteria, with resultant ulcerations, perforation of the intestine and peritonitis.

Various animals are subject to oesophagostomiasis, but in most of them the infection appears to be due to species of parasites other than that which inhabits man. The worms which are commonly found in the intestines of apes and are known as *Oesophagostoma apistomum* have been regarded by Leiper of the London School of Tropical Medicine as identical with the specimens obtained from African natives and originally named *Oesophagostoma brumpti*. The study of the development of the forms found in the monkey has therefore been begun in the Bureau of Science at Manila.¹ The ova can be recovered from the feces, and their development takes place in cultures made in the same manner as for the ova of the hookworm. The larva grows rapidly, and under favorable conditions of culture and temperature attains its maturity in from three to four days. In the process of growth it molts twice. At the last molt the skin is not shed, but remains as a sheath enclosing the larva. In this matured form differing in size and shape from the mature larva of the hookworms and strongyloides, it is ready to infect a new host. Walker points out that this development is strikingly similar and wholly comparable with that of *Ankylostoma duodenale*, which is perhaps to be expected from the somewhat near relationship of the two worms. From this similarity one might expect by analogy that the method

of entrance of the larva into the body of the host would also be similar. The question as to the way in which it attains its position in the tissues of the large intestine can now be solved experimentally, owing to these successful preliminary studies in government laboratories in the Philippines.

ABUSE OF SPECIAL PRIVILEGE

Many of the prominent newspapers of the country have recently been sent printed copies of a committee document from the United States Senate which was printed for the use of the Committee on Public Health and National Quarantine of the second session of the Sixty-Third Congress. Its title is "Arsenization Method of Preventing Yellow Fever," and it is "a memorial praying that publicity be given by the government to the arsenization method of preventing yellow fever as practically demonstrated in the epidemic at New Orleans, Louisiana, 1905." While the matter has merely been referred to the Committee on Public Health and National Quarantine, and the committee has not yet reached any decision in the matter, the first page bears the words "printed for the use of the committee," and the distribution of these committee documents to the newspapers is actually a definite endeavor to secure through the government printing office the publicity prayed for while the matter is before the committee and without waiting for its decision in the matter.

For the proper information of the newspapers it seems to us unfortunate, or at least lacking in that courtesy that publicity seekers should cultivate, that Senate Document No. 111, printed for the second session of the Fifty-Fifth Congress and dated February, 1898, just sixteen years to the month before the subsequent document, was not submitted at the same time to the editorial writers. The title of this is "Arsenization Method of Treating Cholera." The previous memorial also was referred to the Committee on Public Health and National Quarantine in order to be printed. It contained a similar request from the author of the present appeal praying that a test be made of the arsenization method of treating the disease of cholera. The earlier pamphlet is the best possible commentary on the later document which newspapers are now requested to comment on.

Proverbially the hardest thing in the world in logical reasoning is to prove a negative. An immense amount of observation would have to be made in order to demonstrate that the taking of arsenic in certain quantities prevented the development of a specific infectious disease. That it should prevent two such very different specific infections as cholera and yellow fever raises the difficulty of the solution of the problem almost to what mathematicians would call the nth degree. There are almost necessarily millions of people, always hundreds of thousands, in any country

1. Walker, E. L.: The Life History of *Oesophagostomum Apiostomum*: I. Development Outside of the Host, *Philippine Jour. Sc., Trop. Med. (B)*, 1913, viii, 501.

in which such an infection is epidemic, who do not come down with the disease that affects so many of those around them. This has always been true. Their vitality renders them capable of immunizing themselves against the infection. Any of the manifold substances, food materials or drugs that they have been taking might be asserted to be the origin of their immunity. Only the most careful differential investigation under very favorable circumstances for the elimination of disturbing factors would lead to a definite conclusion of any value under such circumstances.

It is interesting to read the account furnished in the latest Senate committee document of the large number of persons who on the bare possibility that arsenic, though in itself a seriously poisonous drug, might help in protecting them from yellow fever, took it in considerable quantities during the epidemic in New Orleans in 1905. The prescription to "take one-one-hundredth of a grain of arsenious acid three times a day for the first week of exposure to infection, twice a day the second week, and once daily thereafter until the remainder of one hundred tablets [why one hundred, except that it is a nice round number, is not clear], granules or powders are taken, or until the epidemic is closed by virtue of sanitary or hygienic precautions or weather conditions" was widely published in the newspapers of the South and "was taken up by the populace of the threatened city in a truly astonishing manner." There was an almost unprecedented rush for the new prophylactic. "Jobbers and wholesalers soon ordered in lots of a million, until upon investigation by representatives of well-known publishing houses it was learned that between fifteen and twenty millions of this particular tablet had been supplied to the trade of New Orleans within the preceding twenty-three days, with many more millions to the trade of outlying infected districts."

Indeed, the only parallel in medical history that we know to such an enormous consumption of a drug is the marvelous spread of the use of tobacco, especially chewing tobacco, when the weed was first introduced. Tobacco was declared to be a wonderful tonic strengthener of the system, a marvelous discovery of the Indians, who by it secured long life and freedom from disease, and above all it was declared to be the most potent of prophylactics. The tradition that was created was so strong that there are still some remnants of it left in the folklore and the popular medicine of all nations. Many a person is still persuaded that to take a chew of tobacco before approaching a small-pox patient or sufferer from other malignant disease is a protective. Undertakers and their helpers still pass on the tradition, in country places at least. In spite of kings and government authorities then and the general condemnation of the learned with even the outspoken disapproval of the church, the use of tobacco spread. That was in the seventeenth century, and we some-

times think that we have progressed beyond the rather childish state of mind which we are inclined to attribute to that period. Incidents like the present raise the question whether or not we have progressed.

In the meantime, the sending of these copies of a document printed at government expense for the use of the Senate committee to the newspapers of the country is an abuse of privilege that deserves severe condemnation. The Committee on Public Health and National Quarantine surely is not willing to allow its privileges to be thus abused, and cannot permit itself to be made a party to this method of securing publicity for a remedy whose efficiency is eminently doubtful and interest in which might well serve to obscure the significance of the true method of preventing yellow fever by eliminating the mosquito, which has been demonstrated to be so effective.

CHOICE OF A MEDICAL SCHOOL

Never before has the choice of a medical school been so simple and easy as at the present time, owing to the abundance of information which is available for the student's guidance. And never was it so important that a careful and wise choice be made.

Formerly the training secured in any medical college was sufficient to give the physician a start in his life work, and to secure a license to practice was also a simple matter. Not so at the present time. Modern medicine is based on scientific knowledge, and without this knowledge the physician of the future will be a failure. To secure such knowledge the student must have a better preliminary education than formerly, and must secure his medical education in a college which has a corps of expert, salaried teachers, well-equipped laboratories and an abundance of dispensary and hospital facilities. Now also definite qualifications are demanded by the various states before the license to practice can be secured.

Before choosing a medical school the student should acquaint himself with the requirements of preliminary and medical education held by the various state licensing boards. These standards have recently been advanced in several states and are bound to be advanced in others in the early future. At present seven states¹ require as the minimum standard of preliminary education two years of liberal arts' college work in addition to a four-year high-school education. In thirteen other states² the minimum standard is one year of collegiate work, in addition to the high-school education. If, therefore, a student is intending to practice in one of these twenty states, it will be necessary for him to have the required amount of preliminary education. If the student needs additional preliminary training, the time to acquire it, of course, is

1. Alabama, Colorado, Indiana, Iowa, Minnesota, North Dakota and South Dakota.

2. Arkansas, California, Connecticut, Kansas, Kentucky, Illinois, Michigan, New Hampshire, Pennsylvania, Rhode Island, Utah, Vermont and Virginia.

before he begins the study of medicine. In fact, this higher preliminary education is now required by all of the better medical colleges. More important, however, a good preliminary education is essential in order that the student may be enabled to master the more complex problems of the modern medical course.

Another very important matter for the student to consider is the character of the college itself. State licensing boards are now making more common use of their legal power to discriminate between medical colleges and to refuse recognition to those which are deemed not properly qualified to furnish a training in modern medicine. Diplomas from those not recognized do not constitute acceptable qualifications for the license to practice medicine in such states. It is important for the student to make sure not only that he has the adequate preliminary education, but also that he shall obtain his training in a medical college which is given recognition in all states.

The question is: How may the student secure the information needed on these matters? Some medical colleges advertise extensively in the newspapers and in popular magazines, and send out announcements and circulars containing very glowing, if not misleading statements. At present several medical schools are being thus extensively advertised, even though their diplomas are not recognized in from twenty-five to thirty states! It is hardly to be expected that the announcements sent out by these schools will convey the information which the prospective students need. It is essential, therefore, that before choosing a medical school, he should secure further information from impartial and reliable sources, so that he may be sure that he is not enticed into a poorly equipped institution and find on graduation that his diploma is not recognized in a large number of states.

An important matter which the student is always bound to consider is the expense. But it is well for him to know that to enter a low-grade medical college because the fees may be a little lower is very poor economy. The truth is that in the same length of time, and often for even lower fees than he would pay in the poorly equipped institutions, he may acquire his education in one of the best-equipped medical schools in the land. This refers particularly to the medical departments of state universities. On the other hand, he should know that even if some of the better schools do charge higher fees, nevertheless, they spend on each student, per year, several times the amount of money that the student pays in tuition. Here again, it would be poor economy to enter a low-standard college which depends on students' fees alone for its income, when for a few additional dollars each year he can enter a thoroughly equipped institution and get a far better medical training. Even should he be required to work his way through college, in whole or in part, the opportunities for doing so are, as a rule, greater in the better than in the lower standard col-

leges. Generally, however, worthy students who are poor in purse are the very ones who appreciate not only the value of money but also the value of the medical course they are getting. Such students are seldom beguiled into a poor college by alluring and misleading advertisements.

In order that the student may be thoroughly informed in any and all of the foregoing matters it would be well for him not only to secure the announcements of a number of colleges among which he may be able to choose, but also to secure reliable information from other sources. He should read carefully the reports on medical colleges published from time to time in *THE JOURNAL* by the Council on Medical Education, which can be obtained in reprint form. After an extensive investigation, including several inspections, the various medical schools have been rated by the Council in four classes, namely, A+, A, B and C, depending on their excellence. If the student is otherwise in doubt, he will not make a mistake by choosing one of the colleges contained in the higher classification. If he has had two or more years of collegiate work in addition to a four-year high-school education, and if he earns his diploma at a college in the higher classification, there is no doubt regarding either the quality of the training obtained or his eligibility after graduation to obtain a license in any state of his choice.

The student must bear in mind that in his preliminary and medical training he is laying the foundation for the rest of his life. If a year or two more is needed to enter one of the better medical colleges, he may count it as time well spent, since he is all the more sure of having laid a solid foundation. The medical profession in this country is extremely overcrowded, but there is always room for physicians who are thoroughly competent. The opposite must not be forgotten: disappointed, indeed, will be that student who, because of alluring advertisements or because of lower entrance requirements, is induced to get his training in a poorly equipped college, and who finds after graduation that he is handicapped for life.

Current Comment

FEWER MEDICAL COLLEGES, STUDENTS AND GRADUATES

The statistics published this week show that in the last decade there has been a marked decrease (about 35 per cent.) in the number of medical colleges and corresponding reductions in the number of students and graduates. Of colleges the decrease was from 165 to 101; of students the decrease was from 28,142 to 16,502 and the number of graduates decreased from 5,747 to 3,594. There are some perhaps, who, not knowing the real cause, may look on these marked reductions with alarm and believe that this country will soon be suffering from a dearth of physicians. Alarming statements to that effect are already being

circulated, but invariably these statements come from those interested in medical colleges conducted more as business enterprises than as educational institutions; those who look more to the incomes from students' fees than to the quality of physicians turned out. There would not have been the marked reductions referred to had it not been for the vast oversupply of medical colleges existing in this country ten years ago. That there is room for a still greater reduction of medical colleges; that there is no cause for alarm regarding a scarcity of physicians, and that the reductions referred to are distinctly in the interests of the public, are clearly evident to any one acquainted with the facts.

REDUCING AN OVERSUPPLY

Prior to the Civil War there had been a rapid increase in the number of medical colleges, there being at the time about sixty in this country. Following the war, however, the number increased by leaps and bounds, until in 1906, not counting the out-and-out diploma mills, a maximum number of 162 colleges was reached. It was then discovered that this country alone had more medical colleges than all other countries of the world combined! The conditions were preposterous. Although an unusual but real demand for doctors, caused by the rapid development and growth of the country, was what originally led to the formation of proprietary medical colleges, nevertheless, not only was the demand soon supplied, but also there came to be so vast an oversupply as to be actually ridiculous. And such colleges! Although there were some fairly good ones, a very large per cent. were joint stock corporations, conducted solely for profit. They were devoid of equipment, few held seriously to any entrance standard, and whoever could pay the tuition fees—the only requirement—was admitted. In order to swell the number of students, and incidentally the income from fees, glowing advertisements were printed and salaried solicitors were sent to offices, work-shops and farms. Large classes were turned out each year after only two short sessions! Is it a wonder that there has been a marked decrease following the quiet but careful investigation of the Council on Medical Education? There is certainly no question that the great reduction in the number of medical colleges and the remarkable improvement in the quality of those remaining will result in a greatly improved medical profession and—more important—will insure for the people better qualified physicians.

NO DANGER OF A SCARCITY OF PHYSICIANS

That the marked reduction in the number of medical colleges during the last decade will result in a dearth of physicians in this country is a proposition which appears ridiculous to any one acquainted with the facts. The normal proportion of physicians to population in the leading nations of Europe is one to every 1,500 to 2,500 people; this country has one physician to every 600 to 850 people. The figures given for this country do not include the osteopaths, Eddyites and other so-called drugless practitioners, which

are scarcely found in other countries. The annual loss of physicians from deaths in this country is approximately 2,000, while the annual output of physicians from the medical colleges for several years exceeded five thousand. Even this year there were 3,594 or nearly twice as many physicians added to the profession as are lost from deaths. It is evident, therefore, that if the annual number of graduates merely replaced the number of physicians removed by death it would still require many years before the supply of physicians would be reduced to the normal quantity needed. Just so long as the colleges continue to turn out more than the number removed by death, just so much longer will it be before the normal proportion is reached. Again, it is apparent that the sixty better medical colleges with their present equipment, and with little if any added expense, could easily take care of all the students at present enrolled in the 101. It is quite clear, therefore, that the number of colleges might be reduced by another fifty per cent. and there would still be no danger of a doctor famine. Thus far we have considered mere numbers. When we consider also the better trained physicians who are now being turned out in place of the product of former years, the danger of a lack of adequate medical service will be pushed still further away. The situation is simply this: A ridiculously large oversupply of exceedingly low-grade, commercial medical colleges with their enormous output of poorly educated doctors is rapidly giving way to a normal quantity—not reached yet—of high-standard educational institutions which are annually turning out a still comparatively large number of more thoroughly trained physicians. There is no question that the change is most beneficial to the public however one may look at it.

MEETING THE SHORTAGE OF IMPORTED DRUGS

Last week we commented¹ on the possible effect of the European crisis on our drug supply, especially the impending shortage of proprietary products (patented or trademarked) of foreign manufacture. As one of the first effects of this shortage physicians will learn that a large number of foreign products sold under proprietary names are available in this country under their non-proprietary, descriptive names if they will prescribe them. Among these may be mentioned dionin, which is offered by American manufacturers as ethyl-morphin hydrochlorid and to be included in the Pharmacopeia under this term; urotropin, which has long been available as hexamethylenamin; and diuretin, available as theobromin sodium salicylate. Atophan is not protected by patent and it is to be hoped that some enterprising American firm will very promptly undertake the manufacture of this product and that American physicians will just as promptly learn to prescribe it under a modified chemical name such as phenyl-quin or any other which may be officially adopted. As regards patented products which are the property of particular foreign firms: It should be demanded of such firms that they take prompt steps to secure the manufacture of these products in this

1. THE JOURNAL, August 15, p. 586.

country as has been done for some years, we are informed, in the case of acetylsalicylic acid (aspirin). If these firms are not in a position to establish factories of their own they will find little difficulty in securing the manufacture of their products by competent American firms. In the meantime Congress should revise the patent law to make it agree with that of most foreign countries; that is, the holder of a patent must under penalty of forfeiture begin manufacture of the patented product in this country in a reasonable period of time after the issuance of the patent. At the same time Congress might properly consider the feasibility of revoking foreign patents on medicinal products if their owners fail to take proper steps to secure for us a supply of the product by manufacture in this country if necessary.

PATENTS ON CERTAIN CHEMICALS EXPIRING

In connection with the shortage of foreign drugs, on which we comment elsewhere, it may be worth while to note that the patent rights on a number of familiar patented products have expired or are about to expire; for instance, the patents on euquinine, pyramidon and protargol have lapsed; those on orthoform-New and aristochin will expire in 1915 and 1916, respectively. Since these products will be public property after the dates indicated, American firms should lose no time in undertaking their manufacture. It should be remembered, however, that if substitutes are to be allowed, standardization should be demanded. Inferior substitutes are a menace greater than the lack of the original products. If salvarsan, neosalvarsan, protargol, etc., are to be made in America, our government should see to it that the American output equals the European product.

Medical News

ILLINOIS

New Officers.—Stark County Medical Association at Toulon, July 27: president, Dr. James R. Holgate, Wyoming; secretary-treasurer, Dr. Clyde Berfield, Toulon.

Illinois Physicians Abroad.—Dr. and Mrs. Harry E. Kerch, Dundee; Dr. James J. Moran, Spring Valley; Dr. Augustus W. Chandler, Rochelle, and Dr. William L. Gray, Champaign, are held in London on account of war conditions.—Dr. and Mrs. William R. Parkes, Evanston, returned from Europe, August 7.

Farm Cottage Annex.—The Illinois Board of Administration has decided to open a farm cottage annex to the Kankakee State Hospital on the site of the new Alton State Hospital. Three farm houses on this property are available, which will accommodate about one hundred patients who have almost recovered their mental poise.

Kane County Board Takes No Action.—Supervisor George F. Sills of Kane County calls attention to an error in THE JOURNAL of August 8, page 491. The committee of supervisors, as then stated, have prepared a report opposing the establishment of a county sanatorium, but no action has been taken on this report as there will be no meeting of the board until September.

Chicago

Personal.—Dr. John P. Sprague has been appointed professor of physical education and hygiene at Grinnell College, Grinnell, Iowa.—Dr. Otto L. Schmidt has been elected commodore of the Northwestern Yachting Association and of the Inland Lakes Yachting Association.

Home from Abroad.—The following physicians of Chicago have recently returned from abroad: Dr. and Mrs. Harry J. Stewart, Dr. Casey A. Wood, Dr. and Mrs. Junius C. Hoag, Dr. Wilhelm E. Krieger, Dr. Raymond W. McNealy, Dr. and Mrs. Edward L. Webb and Dr. Jabez D. Hammond.

Physicians Still Detained Abroad.—The following additional names of physicians detained abroad on account of the difficulty of obtaining passage by reason of war conditions are: Dr. and Mrs. Peter C. Schenkelberger, Dr. Paul Owsley, Dr. and Mrs. Alfred Schirmer and daughter, Dr. Ernest A. Loewinger, Dr. Robert H. Buck and Dr. Michael Goldenburg.

Cook County Hospital Opened.—The first building of the new Cook County hospital was opened August 15 without ceremony. The building at present in use is the administration hall which will accommodate 656 patients. The entire eighth floor of the building is arranged for surgical work. There are nine operation rooms including two amphitheaters. The silent-call signal system has been installed throughout the institution. The old hospital buildings are now to be wrecked to make room for the new structures which will cost when completed, \$16,000,000.

KENTUCKY

State Association Meeting.—The annual meeting of the Kentucky State Medical Association will be held at Newport, September 24-26, with headquarters at the Carnegie Hall.

Personal.—Dr. Arthur L. Nelson has succeeded Dr. Evan E. Owen as secretary and assistant superintendent of the Louisville City Hospital.—Dr. David C. Morton, Louisville, professor of medicine in the University of Louisville and chairman of the City Hospital Committee, has resigned and retired from practice.

Pellagra Conference.—A pellagra conference was held by the State Board of Health in connection with the annual school of city and county health officers at Pineville, August 18 to 20. In addition to the study of pellagra there was an unusual clinic, and the duties of physicians and health officers under the new law in regard to trachoma and other diseases leading to blindness were fully discussed and explained. Special attention was also given to the study of the sanitation of small towns and country districts with a view to the prevention of typhoid fever.

MASSACHUSETTS

Insanity Board Organized.—The new Board of Insanity created under the law relative to the organization and powers of the State Board of Insanity, which went into effect August 1, was organized August 10, with Dr. Michael J. O'Meara, Worcester, president; Dr. L. Vernon Briggs, Boston, executive secretary, and M. Charles E. Ward, Buckland, as the third member. The appointments were made by the governor early in August.

Personal.—Dr. Milo A. Jewett has been appointed United States consul at Kiel, Germany.—Dr. Max Baff, Worcester, has returned from abroad.—Drs. Henry M. Chase and Hilbert F. Day have been appointed surgeons in charge of the Boston Dispensary to fill the vacancies caused by the retirement of Drs. Benjamin Tenney and John Homans, who have been placed on the consulting staff of the institution.—Dr. Simon F. Cox, superintendent of the Tuberculosis Hospital, Mattapan, since 1906, has accepted the position of superintendent of the New Haven hospitals.—Dr. Walter Channing, Brookline, a trustee of the Boston State Hospital, has resigned.

MICHIGAN

Hospital Merger.—Solvay General Hospital, Detroit, with a capacity of fifty beds was merged with the Harper Hospital, August 3. The merged institutions will be under the care of Dr. Wayne Smith, superintendent of the Harper Hospital.

Personal.—Dr. F. Elizabeth Barrett has succeeded Dr. Claude B. Fulkerson as medical inspector of the public schools of Kalamazoo.—Dr. Duncan McKellar, Hillsdale, who has been suffering eight weeks from septicemia, had his right leg amputated recently.

Veteran Honored.—Dr. Theodore A. McGraw, Detroit, in recognition of forty-five years of continuous service as a member of the medical board of St. Mary's Hospital, was honored June 30 by fifty of his associates who presented him with a silver vase as a token of love and appreciation from his co-workers in the hospital.

Michigan Physicians Abroad.—Drs. Ross U. Adams, Kalamazoo, and Francis H. Callow, Mt. Morris, have returned from Europe.—Dr. William F. Hake, Grand Rapids, is reported to have sailed from Europe August 6.—The following Michigan physicians are believed to be held in London by reason of the war situation: Drs. Charles H. Oakman, Angus McLean, James M. Robb, Roland E. Loucks, Ernest W. Haass, Max Ballin, George E. McKean, Don M. Campbell, Alexander W. Blain and J. Everett King, Detroit, and Drs. Charles E. Boys, Kalamazoo, Charles H. Baker, Bay City and Arthur L. Robinson, Allegan.

MINNESOTA

Medical Block Again Burned.—The third fire in four months in the Medical Block, Minneapolis, August 7, did damage amounting to \$35,000.

New Officers.—Wabasha County Medical Society at Elgin, July 9: president, Dr. William B. Heagerty, Mazeppa, secretary-treasurer, Dr. William F. Wilson, Lake City.

Minnesota Physicians Abroad.—Dr. William R. Murray, Minneapolis, and Dr. Charles H. Mayo, Rochester, have returned from Europe.—Dr. Charles W. More, Eveleth, Louis A. Fritsche, New Ulm, Frank C. Davis, Minneapolis, and Rowland Gilmore, Bemidji, are believed to be detained in Europe on account of the war conditions.

Personal.—Dr. Ernest A. Anderson, Holdingford, has been elected a member of the board of supreme medical directors of the Modern Woodmen of America with his office at Rock Island, Ill.—Dr. H. G. Lampson has resigned as health officer of Rochester.—Dr. G. W. Moore has been elected mayor of Hopkins.—Dr. Rollo C. Dugan, Winona, has been appointed superintendent and chief surgeon of the hospital recently established in Ottawa, Kans., by the Businessmen's Association of that city. The hospital is located in the old Semple Sanitarium building.

NEW YORK

Sanitary Conference.—The annual sanitary conference of the State will be held in Saragota, September 15 to 17. In addition to the meeting of health officers there will be a sectional conference for registrars of vital statistics.

To Bar Useless Germicides.—A bill is being prepared by Senator William J. Heffernan of Brooklyn for introduction at the next session of the legislature to stop the sale of useless disinfectants. It is claimed that about 25 per cent. of the disinfectants now used are worthless. Maryland is the only state thus far having a law dealing with the sale of disinfectants.

New York City

Fewer Deaths Among Infants.—During the first week in August the total number of deaths among infants under one year of age was 331, or fifty less than during the corresponding period of 1913. Manhattan led in the decrease with 167 deaths as against 198 for the corresponding week of last year.

Brooklyn Hospital Purchases Site.—The Williamsburg Hospital, which has been located on Bedford Avenue for half a century has purchased a site for a new hospital at South Ninth Street and Driggs Avenue. It is intended to erect a modern hospital building early next year which it is expected will cost \$125,000.

Personal.—Dr. Alexis V. Carrel of the Rockefeller Institute of Medical Research, who has been visiting his home at Lyons, France, has gone to the front as a surgeon with the French army.—Dr. Moses Kahn has resigned from the resident staff of Sea View Hospital to accept the position of assistant physician in charge of tuberculous cases at the Eloise Infirmary, Eloise, Mich.

High Cost of Food and School Children.—Dr. Sigismund S. Goldwater, Health Commissioner, announces that he proposes to make an investigation of the effect of the increased cost of food on the health of school children. The nurses who visit the school are to make a general examination in September and to make inquiries into the cause of lack of proper nourishment. The information presented will be submitted to the Mayor's Committee.

PENNSYLVANIA

Personal.—Dr. Mary M. Wolfe, Lewisburg, has been appointed superintendent of the State Institution for the Care of Feeble-Minded Women, near Hartleton.

Detained in Europe.—Drs. Oskär Klotz and James D. Heard, Pittsburgh, and Martin E. Griffith, Monessen, are detained in Europe on account of the prevalent war conditions.

Philadelphia

Personal.—Dr. McCluney Radcliffe received the degree of LL.D. from Pennsylvania College, Gettysburg, in June.—Dr. J. E. B. Buckenham was provisionally appointed as acting chief resident physician at the Philadelphia Hospital for Contagious Diseases, during the absence of Dr. S. S. Woody, on vacation.

Changes at Polyclinic Hospital.—At the last meeting of the board of managers, Dr. Thomas B. Holloway was elected professor of ophthalmology to succeed Dr. James Thorington, resigned; Dr. Charles R. Heed was elected associate professor of ophthalmology; Dr. George S. Crampton was made lecturer on refraction.

Raid on Doctored Drinks.—A determined crusade, supported by the Phipps Institute, where several children are seriously ill from saccharine poisoning, and the child federation, resulted in the arrest, August 13, of twenty-eight persons in the downtown section of the city. Fourteen of them admitted their guilt and were fined \$28 to \$32 by Magistrate Rooney. Seven cases were continued and seven other violators of the pure food law paid the costs and signed the agreements to quit the business.

Crusade Against Rats.—As several deaths from bubonic plague have occurred in Liverpool, precautions are being taken at this port to prevent an introduction of the disease. Dr. Fairfax Erwin, in charge of the United States Marine Hospital here and Dr. Henry D. Heller of the State Quarantine Board, asked the cooperation of the Health Department to begin a war on rats which infest the river front. Following a conference of Chairman Connelly of councils finance committee and City Controller Walton, August 14, it was announced that \$10,000 would be placed at the disposal of Director Harte of the Bureau of Health and Charities for this purpose.

TENNESSEE

New Officers.—Sullivan, Carter and Johnson Counties Medical Society, organized at Johnson City, July 23: president, Dr. Edward S. King, Bluff City, Sullivan County; vice-presidents, Drs. Edwin E. Hunter, Elizabethton, and David R. Butler; secretary, Dr. Conley M. Cowan, Bristol. The next meeting will be held at Bluntville.—State Association of Colored Physicians at Dickson: president, Dr. F. A. Stewart, Nashville; secretary, Dr. Isham H. Hampton, Fayetteville. The next meeting will be held in Nashville.

Personal.—Dr. William D. Haggard, Nashville, returned from Europe on the *Mauretania*.—Dr. Reynold M. Kirby-Smith, Sewanee, has been selected by the American National Red Cross to direct the relief work in one of the belligerent countries of Europe.—Dr. Walter Stewart, Bolivar, has been appointed superintendent for the West Tennessee Hospital for the Insane, succeeding Dr. James J. Neely, resigned. Dr. Edwin W. Cocke, Whiteville, has been appointed assistant superintendent.—Drs. John S. B. Woolford and Henry Berlin, Chattanooga, have been detained in London on account of war conditions.—Dr. James W. Gillespie, for fourteen years coroner of Hamilton County, has resigned and Dr. John J. Gee has been elected his successor.—Dr. Otis M. Hayward, proprietor and president of the Chattanooga Hospital, has accepted the presidency of the Hurlbut Sanitarium and Industrial School, Reeves, Ga.—Dr. Z. D. Massey, physician at the State Prison, has resigned and will resume practice at his old home in Sevierville.

TEXAS

New Officers.—Dallas Medical and Surgical Society, July 25: president, Dr. Oscar M. Marchman; secretary, Dr. Franklin A. Pierce.

Fund for Medical College.—A fund of \$40,000 was subscribed for the medical department of the Texas Christian University, Fort Worth, July 23.

Dinner to Surgeon General.—In honor of Surgeon General Rupert Blue, U.S.P.H.S., the Sisters of the Incarnate Word, Galveston, gave a dinner July 13.

Tuberculous Convicts Pardoned.—Thirty convicts in the Texas State Penitentiary in an advanced stage of tuberculosis, have been pardoned by the governor.

Emergency Hospital Provided.—The United States Quarantine Station, Pelican Island, is being fitted up as a possible Emergency Hospital for contagious diseases with especial reference to bubonic plague.

Dr. Osborne not Dead.—Dr. Frank Ely Osborne, McAllen, Texas, states that the notice of his death which appeared in THE JOURNAL of August 15, is incorrect; that another person of the same name was in the automobile accident.

Work on Epileptic Colony to Begin.—Plans for the first of the two new buildings for the Epileptic Colony which will be established south of Abilene, have been received and construction work has been commenced. The buildings are to be two stories and basement in height and will be located on the southwest corner of the colony grounds.

Sanitarium News.—An addition to the Texas Baptist Memorial Sanitarium, Dallas, has been erected at a cost of \$30,000. The building is to be used for negroes, Mexicans and indigent white patients.—The sanitarium at Sutherland Springs which is being erected at a cost of \$10,000 is almost completed.—A cottage for consumptives has been erected at the North Texas Hospital for the Insane, Terrell.—Plans are being prepared for an addition to the St. Paul Sanitarium, Dallas.

Personal.—Drs. Hugh W. Crouse, El Paso and Robert S. Killough, Amarillo, have been detained in Germany on account of the war.—Dr. Henry A. Barr, Beaumont, has returned from abroad.—Dr. Bacon Saunders, Chief Surgeon of the Trinity and Brazos Valley Railway and Dr. Roy Saunders, Assistant Chief Surgeon, Ft. Worth, have resigned. Dr. A. Philo Howard, Houston, has been appointed Chief Surgeon for the Road.—Dr. Thomas J. Milner, Greenville, has been appointed medical director with the rank of Major in the Third Brigade Texas Division, United Confederate Veterans.—Dr. Paul Renger has resigned as health officer of Hallettsville to accept the position of health officer of Lavaca County.—Dr. Charles H. Brownlee, Austin, has resigned as field director of the Texas Hookworm Commission and will reenter practice at his old home in Burnett.

GENERAL

Hospital Experts to Meet.—The annual conference of the American Hospital Association will be held in St. Paul, August 25-28, with headquarters at the Hotel St. Paul.

Electro-Therapeutists to Meet.—The annual meeting of the American Electro-Therapeutic Association will be held in Battle Creek, Mich., September 15 to 17, under the presidency of Dr. George E. Pfahler, Philadelphia.

Anesthetists Elect Officers.—At the annual meeting of the American Association of Anesthetists held in Atlantic City recently, the following officers were elected: Dr. Charles K. Teter, Cleveland, president, and Drs. Mary V. Madigan, Portland, Ore., W. D. Galch, Indianapolis, and T. B. Buchanan, New York City, vice-presidents.

Fraternal Order's Work Against Tuberculosis.—The Loyal Order of Moose at its convention in Milwaukee, which closed July 31, decided to withdraw the appropriation of \$125,000 which had been given annually to the official publication, "The Call of the Moose," and to use the money for the establishment and maintenance of a sanatorium for its members suffering from tuberculosis.

Retired Naval Surgeons Abroad.—The following retired officers of the medical corps of the United States Navy are reported to be abroad: Med. Dir. John C. Wise at Bordeaux, Surgeon General William K. Van Ruyphen, Med. Dir. Henry G. Beyer, Dwight Dickman, David Kindleberger and Averly C. H. Russell, Passed Assistant Surgeon Paul E. McDonnold and Assistant Surgeon Arthur C. Stanley, in London.

Bequests and Donations.—The following bequests and donations have recently been reported:

Methodist Hospital, Philadelphia, \$5,000 by the will of Miss Hessa R. Miller for the maintenance of a free bed.

The Philadelphia Home for Incurables, \$15,000 by the will of Mary J. Van Syckel, for the maintenance of two free beds.

German and St. Mary's Hospital, Philadelphia, an equal donation of the property owned by the late Mrs. L. Gluck at Twenty-fourth and Stanley Streets.

Post-Graduate Hospital, New York City, \$5,000 by the will of Miss Cora V. C. Catlin in memory of her brother John M. Catlin.

Dr. Gerald R. Maloney, Belleplaine, Minn., property valued at \$400,000 by the will of Monsignor Thomas Kennedy.

Old Peoples' Home, Omaha, Neb., a donation of \$5,000 toward an endowment fund in memory of Mrs. Ida V. Tilden, Oswego, N. Y., City Hospital, \$10,000; New York Association for Improving the Condition

of the Poor and St. Luke's Hospital, New York City, each \$25,000 by the will of George E. Sloan of Oswego.

American National Red Cross, Colorado Chapter, donation of \$1,000 by Lawrence C. Phipps, Denver.

The Plague Situation.—The last case of human plague reported from New Orleans was that of Rosie Southern, reported July 22 and officially diagnosed July 26. Four more cases of plague have been diagnosed since that time and the particulars of these are given below, together with the cases of rodent plague and the details of the work which is being so actively conducted in New Orleans by Assistant Surgeon-General William Colby Rucker, U.S.P.H.S., and his efficient staff with the intelligent and active cooperation of the health authorities of the state of Louisiana and the city of New Orleans. Case No. 14, Henry Chase, male, colored, 22, residing 2136 Eighth Street, car cleaner, working in the L. & N. shops, Girod and Front streets. Sickened July 29, 1914. Right femoral bubo. Officially declared plague Aug. 2, 1914. Case No. 15, Mrs. J. Bua, female, white, 20, residing 1836 Iberville Street, and working at the same address in a grocery. Sickened Aug. 11, 1914. Left femoral bubo. Officially declared plague Aug. 12, 1914. Case No. 16, Anthony Gergurovich, white, male, residence 1817 Carondelet Walk, employed at French market, sickened August 8, left inguinal bubo, diagnosis confirmed August 13. Case No. 17, Herman Schulz, white, male, age 17, residence 1836 Iberville Street, employed at same address, sickened August 1, diagnosis confirmed August 13, right femoral bubo. Cases 15 to 54 of rodent plague have been reported up to August 15. The infected rats were found in the same general localities as heretofore. From the beginning of the work on July 9, 1914, up to and including Aug. 12, 1914, there were captured in traps 42,214 rats, and in the same period a conservative estimate of the number of rats destroyed by the antiplague workers is 60,000. The campaign of publicity and education has been carried forward very vigorously. Three and four public addresses have been made each day, many of them illustrated by means of stereopticon views. As a result, there has been formed an organization in each of the seventeen wards of the city, each of which has established a precinct captain, under whom are monitors for each block. The commissioner of public property, the Honorable E. E. Lafaye, with Assistant Surgeon-General W. C. Rucker, has formed committees for the conduct of clean-up days in the various wards. Several wards have already been treated, and the work will be extended throughout the entire city. Public cooperation has been very extensive, and thousands of yards of concrete and other rat-proofing material are being laid throughout the city, and the city is rapidly becoming more sanitary. Advantage has been taken of the billboards of the city to extend the publicity campaign. There is one large night and day sign 30 feet long by 12 feet high located on Canal Street, and there are distributed throughout the city 400 posters, 42 inches by 84 inches, calling on the citizens to unite in the sanitary campaign. The inspection of outgoing freight has been extended, and there are now employed in this work one chief inspector and eighty-two assistant inspectors. The citizens' committee, which was appointed by Mayor Behrman, was reorganized on August 6 as the Citizens' Health Committee, with Mr. Crawford Ellis as chairman. This committee consists of the original fifteen members appointed by the mayor and seventeen members representing the various wards of the city; a special committee on sanitation, of which Dr. H. Dickson Bruns is chairman; a committee from the New Orleans Parish Medical Society, of which Dr. Jos. Scott is chairman; a committee from the Pan-American Medical Society, of which Dr. Hochfeldt is chairman; the state health officer, the city health officer and the officer in command of the United States Public Health Service are also members of this committee. The committee meets each Thursday for the purpose of considering cooperative work of the campaign. It is anticipated that the women's clubs of the city will be given a representative on the Citizens' Health Committee. During the fortnight ended August 8, 219 vessels were fumigated; 21,827 pounds of sulphur were burned; 172,917 tons of outgoing freight were inspected; 45 clean bills of health and 10 foul bills of health were issued. The overland freight inspection during the same period included 9,888 cars; the rat-proofing of 3,272 cars; the condemnation of 18 cars and the killing of 13 rodents in cars. In the field operations 19,405 rats were trapped, 227 dead were inspected; 18 buildings were fumigated; 33,910 poisons were placed, and 3,926 buildings were inspected. In the laboratory 18,670 rats were examined out

of 20,752 received; of these 61 were suspicious and the diagnosis of plague was confirmed in 29. The following circular letter regarding shipment of merchandise was issued August 4:

To Shippers, Agents and Others Concerned, City of New Orleans, La. For your guidance, and in order to prevent unnecessary hindrance to commerce, you are informed that, in compliance with United States Statutes At Large, Vol. 27, page 449, Act of February 15, 1893, no merchandise shall be permitted shipment from New Orleans, except it be so protected as to exclude rats.

This applies especially to merchandise in crates, barrels, hampers or boxes, and packed with excelsior, straw, paper or burlap.

Containers must be so closed at the time of packing as to effectually exclude rodents, and to this end the Service inspectors stationed at the various railroad freight terminals have been instructed to prohibit the loading of any freight not conforming to the above requirements.

W. C. RUCKER, Assistant Surgeon General, Commanding.

FOREIGN

Hospital Ship Commandeered.—The British Steamer *Protesilaus* which stopped at Victoria, August 5, on the way from China to Seattle, was boarded by British officers who took command, and ordered her to discharge her cargo of silk. She was then taken to the Esquimaux navy yard where she will be equipped as a hospital ship.

Medical Regulations in Korea.—The American consul general at Seoul has forwarded to the Bureau of Foreign and Domestic Commerce, Washington, a translated copy of the recent orders of the government of Chosen for the control of physicians, dentists, Korean old-style physicians and supernumerary medical advisers or public health officers. These regulations became effective the first of the year.

Medal for Oswaldo Cruz.—The last *Brasil Medico* gives an illustration of the square plaque with a bas-relief bust of Cruz and an allegorical figure on the reverse which was recently presented to him with much ceremony in the name of the Seventh Brazilian Medical and Surgical Congress. To Oswaldo Cruz belongs the honor of the sanitation of Rio de Janeiro which has eradicated yellow fever and transformed its public health record in general; also the more recent sanitation of Para in the rubber district. He has also stamped out plague wherever it has obtained a foothold in Brazil in late years.

Offer to Establish Hospitals.—Mrs. Sarah Wilson and Mrs. George Keppel have offered to establish a French-English hospital at LeTouquetor whenever the French government deems it advisable. The hospital will contain 2,000 beds and will be maintained as long as the war lasts. —The American Ambulance Corps in Paris has secured a building in Neuilly which is to be transformed into a hospital. Twelve American physicians headed by Dr. Joseph A. Blake, New York City, and twenty-four nurses, have volunteered for service and \$9,000 has already been subscribed for the maintenance fund.

Student Congress in Latin America.—The fourth international biennial Pan-American congress of university students is to be held at Santiago in September. The third meeting was at Lima in 1912. There are eleven subjects appointed for discussion at the approaching congress, including suggestions for reforms in the curriculum and methods; higher education of women; the problem of sexual relations from the point of view of the student; comparison of conditions in regard to sanitation and hygiene in the various countries of America, and conditions in regard to professional and industrial life as affecting choice of a career. Rafael Capurro of Lima, Peru, is one of the secretaries of the Oficina Internacional Universitaria Americana.

CANADA

Indemnity Claims.—The late typhoid fever epidemic in Ottawa, Ont., resulted in the preferring of 2,500 claims for indemnity against the Ottawa city council. Of these 681, representing an amount of nearly \$35,000, have been passed for payment.

New Officers.—Alberta Medical Association ninth annual meeting at Medicine Hat July 16 and 17: president, Dr. Robert G. Brett, Banff, secretary, Dr. F. C. Clarke, Calgary. —Vancouver, B. C., Medical Society: president, Dr. William D. Keith, secretary, Dr. J. H. MacDermot.

Dominion Physicians Meet.—The Canadian Medical Association held its annual meeting in St. John, N. B., in July. The next annual meeting will be held in 1915 in Vancouver, B. C., with Dr. R. E. McKechnie, Vancouver, as president. Dr. William W. Francis, Montreal, was re-elected secretary.

New Legislators.—In the recent Manitoba elections the following members of the medical profession were elected to the legislature of that province: Drs. Robert S. Thornton, Deloraine; Dr. McFadden, Emerson; Hon. Dr. W. H. Montague, Minnedosa; and Drs. Armstrong and George Clingan, Virden.

Canadian Physicians Abroad.—Word has been received from Dr. J. George Adami of McGill University that he is at present in Switzerland but will return to London as soon as possible. —When last heard from President Falconer of the University of Toronto was in Sweden. —Mr. Irving Heward Cameron, professor of surgery in the University of Toronto, is in London, England, and expects to return to Toronto in September.

Offer Services for War.—Drs. D. A. McLennahan, Hamilton, David B. Bentley, Sarnia, and Robert E. Wodehouse, Fort William, district officers of health in Ontario, have signified their intention of relinquishing their public health duties and going abroad with Canada's first contingent to the European war. —Dr. John A. Amyot, provincial bacteriologist and professor of public health in the University of Toronto, has offered his services to the federal government for like service.

Personals.—Dr. Samuel J. Streight, Welland, Ontario, has gone abroad for a year. —Drs. Alan G. Brown and J. George A. Campbell have been appointed directors of Child Hygiene, Department of Public Health, Toronto. —Dr. Herbert E. Clutterbuck, Toronto, is doing graduate work in Edinburgh. —Dr. W. Ewart Ferguson, associate editor of *The Canada Lancet*, Toronto, has sailed for Europe. —Dr. David Jamieson, Durham, member for South Grey in the Ontario Legislature is to be the next speaker of that body.

LONDON LETTER

LONDON, July 31, 1914.

THE CLINICAL CONGRESS OF THE SURGEONS OF NORTH AMERICA

(Continued from page 592)

Annual Executive Session

At the annual executive session Dr. Davidson of Illinois presented a report on the standardization of surgery. He said that this should take place on the lines of education and legal enactment modifying and amending the various practice acts in the different states. Dr. Jeff. Miller, New Orleans, presented a report from the committee on cancer. Dr. A. B. Kanavel, Chicago, presented a report on the standardization of hospitals. He said that the replies obtained in answer to a circular from the various hospitals, especially the large hospitals, showed that the project was received with favor. Work should be done by cooperation of the American Medical Association, the American Hospital Association, the Carnegie foundation and various medical educational bodies. The measures proposed were (1) an end-results card catalog, (2) a follow-up system, and (3) an efficiency committee composed of members of all branches of hospital management. A hospital which refused to admit and record its failures and to analyze the reasons for the failure to give relief was not doing its duty. The following officers were elected: president, Charles H. Mayo, Rochester, Minn.; first vice-president, Herbert Bruce, Toronto; second vice-president, R. L. Dickinson, Brooklyn; secretary, F. H. Martin, Chicago; treasurer, A. B. Kanavel, Chicago; general manager, Albert Ballou.

Suture of Levator Ani in Perineorrhaphy

Dr. Henry Jellett, Dublin, opened a discussion on this subject. He pointed out that the levator ani was an essential constituent in the pelvic floor, but none of the older methods provided a means for its suture and many of the present generation of gynecologists continued to practice them because they thought suture of the muscle was difficult and not devoid of danger. Certain writers had introduced unnecessary complications into an operation which was really very simple. The essential features of the operation were as follows: (1) The careful dissection of the necessary amount of vaginal mucous membrane off of the rectum; (2) the exposure and suture of the separated levator ani muscles, and (3) the careful approximation of the cut edges of the vaginal mucous membrane so as to leave no projection or redundancy. The operation was carried out as follows: The extent of the

perineal tear was carefully determined, and its anterior edges were marked out by bullet forceps. A third bullet forceps was applied to the perineal skin just behind the posterior edge of the tear. The position of the separated edges of the levator ani was palpated through the mucous membrane of the vagina. An incision was then made from side to side along the line of junction of the skin and the vaginal mucous membrane. This incision cut through the skin and any underlying scar tissue. A flap of vaginal wall was then dissected up off the underlying rectum. At its lowest part it was firmly held to the rectum and the sphincter ani by cicatricial bands, the result of the healing. As soon as these had been cut through, the separation of the remainder of the flap by blunt dissection was easy. When the dissection of the flap was complete a triangular space was exposed, which was bounded laterally below by the remains of the superficial vaginal and perineal muscles, and at a deeper level by the pubococcygeal fibers of the levator ani muscle, while its floor was formed by the rectum. It was then easy to catch the edges of the levator with clip forceps or dissecting forceps, and to draw them downward and inward until they met in the middle line. If the separation and atrophy of the muscle were marked it might not be possible to draw the edges down sufficiently, but in the great majority of cases they could be brought into view. Three or four interrupted sutures of catgut were then passed through them from side to side, so that when tied they would approximate them in the middle line; for the present, however, they were left untied. The next step was to trim the vaginal flap into proper shape, so that when the operation was complete there might be no redundancy. The cut edges of the flap were then brought together by a continuous catgut suture passed from above downward, and ending at the vulvar orifice. This being done, the catgut sutures in the levator muscle might be tied. The last step consisted in the introduction of silkworm-gut sutures passed so as to close the skin edges of the perineal wound. These sutures were passed from side to side, and traverse the skin and the remains of the superficial perineal muscles, and also the levator muscle so as to supplement the buried sutures.

Transplantation of Ovaries

Professor Tuffier, Paris, read a paper on this subject. The grafting of ovaries from one patient into another was difficult, but might become successful with the improvement of technic, and possibly some chemical substance might be found to protect the implanted ovary from the action of the phagocytes. He described the procedure of grafting the patient's own ovaries into the subperitoneal fatty tissue, the uterus being left *in situ*. The graft could be made in the neighborhood of the uterus or elsewhere. The abdomen was opened, adhesions broken down; the ovary, tubes and glands were isolated; the ovary was then dissected out and embedded in a pouch formed in the subperitoneal fat. The fallopian tubes were then removed. Complete hemostasis was important and asepsis was necessary; otherwise the grafts became cystic or sclerosed. If necessary, the gland could be divided into two parts and each portion engrafted. The implanted ovaries remained inactive for about three or four months after operation, and symptoms of climacteric commenced; then for four or five days the ovary became painful and menstruation recommenced. There was usually a period of six months between the operation and the establishment of menstruation.

(To be continued)

Marriages

GEORGE REED TADOR, M.D., Crystal Springs, Tex., to Mrs. Augusta Jones Hunting of Houston, Tex., at Birchmont, North Conway, N. H., July 29.

EDWARD N. BRUSH, M.D., Towson, Md., to Miss Marie Tregoe Hartman of Forest Park, Md., August 6.

ALBERT CLIFFORD HIRSCHFELD, M.D., Norman, Okla., to Miss Florence Kynette of Dallas, Tex., July 5.

VICTOR ERRILL BELLINGER, M.D., Mt. Pleasant, Iowa, to Miss Regina Kelley, at Des Moines, Iowa, July 26.

EDWARD KENT ARMSTRONG, M.D., Chicago, to Miss Caroline Holmes Focer of Cape May, N. J., August 10.

ALICE JOSEPHINE B. HOPKINS, M.D., and Mr. Clarence Carl Tolg, both of Madison, Wis., June 6.

Deaths

Alfred Mercer, M.D. Geneva, N. Y., Medical College, 1845; a Fellow of the American Medical Association; dean of the medical profession of central New York; professor of minor and clinical surgery, and later professor of state medicine and emeritus professor of medicine in Syracuse University College of Medicine; once president of the Syracuse Medical Society, Onondaga County Medical Society and Syracuse Academy of Medicine, vice-president of the Medical Society of the State of New York and treasurer of the Medical Society of Central New York; a member of the British Medical Association and American Public Health Association; a member of the State Board of Health for five years and of the Syracuse Board of Health for seven years; than whom no medical practitioner in the state was held in greater respect and love; died at his home in Syracuse, August 5, aged 93.

William Henry Carr, M.D. University of Pennsylvania, Philadelphia, 1883; a Fellow of the American Medical Association; a specialist in diseases of the eye, ear, nose and throat; for two years resident physician at the Schuylkill County Hospital; died at his home in Lancaster, Pa., August 2, from injuries sustained in a fall some time before.

Victor Clay Barringer Means, M.D. New York University, New York City, 1882; retired Lieutenant Commander, U. S. N.; a Fellow of the American Medical Association; since his retirement, in 1908, a resident of Philadelphia; died in the U. S. Naval Hospital, Washington, D. C., July 18, aged 54.

Phillip F. Dillon, M.D. Minnesota Hospital Medical College, Minneapolis, 1886; a member of the Rhode Island Medical Society; for sixteen years surgeon to the Soldiers' Home, Bristol, R. I.; a veteran of the Civil War; died at the home of his sister in Anacortes, Wash., July 31, aged 72.

Matthew Joseph O'Connell, M.D. Niagara University, Buffalo, N. Y., 1890; a Fellow of the American Medical Association and superintendent of an institution for the treatment of liquor and drug addiction in Buffalo; died in the institution, August 4, from acute gastritis, aged 52.

Walton Bolgiano, M.D. University of Pennsylvania, Philadelphia, 1892; a Fellow of the American Medical Association; for several years a member of the staff of the Presbyterian Hospital, Philadelphia; died at his home in Baltimore, August 2, from heart disease, aged 46.

Isaac W. Hazelett, M.D. Jefferson Medical College, Philadelphia, 1879; a specialist on diseases of the eye, ear, nose and throat; local surgeon of the Santa Fe System at San Bernardino, Cal.; died in the Pacific Hospital, Los Angeles, August 4, from pneumonia; aged 58.

William I. Wood, M.D. University of Worcester, Cleveland, Ohio, 1888; for ten years a practitioner of Massillon, Ohio, but for a month a resident of Seville, Ohio; died in the German Hospital, Cleveland, August 8, after an operation for appendicitis, aged 56.

Michael W. Raub, M.D. Jefferson Medical College, 1865; a member of the Medical Society of the State of Pennsylvania and a noted ornithologist; curator of Franklin and Marshall College, Lancaster, Pa.; died at his home in Lancaster, August 8, aged 78.

Dryden Hemingway Lamb, M.D. University of Michigan, Ann Arbor, 1891; a Fellow of the American Medical Association and a specialist on diseases of the eye, ear, nose and throat; of Owosso, Mich.; died at his home in that city, about August 5.

Edmond M. Cahen, M.D. University of Southern California, Los Angeles, 1908; a Fellow of the American Medical Association; of Los Angeles; died in that city August 4, it is believed by suicide while despondent over business affairs, aged 29.

Phaon D. Keiser (license, Carbon County, Pa., 1881), for fifty-three years a practitioner of Carbon County; a member of the Medical Society of the State of Pennsylvania; died at his home near Lehighton, Pa., July 31, aged 76.

William Henry Eldred, M.D. Rush Medical College, 1882; Hahnemann Medical College, Chicago, 1883; died at his home in Chicago, August 12, aged 56.

Glenn Orville Hymer, M.D. Marquette University, Milwaukee, Wis., 1910, of Williston, N. Dak.; died in Madison, Minn., July 23, aged 28.

Charles Heselton Foster, M.D. Dartmouth Medical School, Hanover, N. H., 1875; for more than thirty years a practitioner of Lisbon, Maine; died at his home in Riverside, Cal., August 2, from pneumonia.

Cleveland Stuart Stilwell, M.D. College of Physicians and Surgeons in the City of New York, 1875; a director of the Peconic Bank and a retired practitioner of Sag Harbor, L. I., N. Y.; was found dead at his home August 6, from asthma, aged 61.

Daniel McD. Yount (license, North Carolina), a practitioner for fifty-five years; a Confederate veteran; twice a representative in the legislature from Catawba County; died suddenly at his home in Conover, N. C., August 8, aged 81.

Elmer Ellsworth Finch, M.D. Albany, N. Y., Medical College, 1886; a member of the Medical Society of the State of New York; died at his home in Schodack Center, N. Y., July 18, aged 48.

John Albin Hamilton (license, Washington, 1900) of Seattle; a practitioner since 1897; died recently from septicemia following an accidental gunshot received while hunting in Alaska.

William F. Richardson, M.D. American Medical College, Eclectic, St. Louis, 1871; of Pierce City, Mo.; died in Carthage, Mo., August 5, from pulmonary hemorrhage, aged 75.

Henry Hersey Mothersbough, M.D. University of Pennsylvania, Philadelphia, 1879; formerly of Beech Creek, Pa.; died at his home in Altoona, Pa., August 1, from nephritis, aged 70.

Lafayette Coffman, M.D. Maryland Medical College, Baltimore, 1905; a member of the Oklahoma State Medical Association; died at his home in Peggs, Okla., August 3, aged 44.

Albert Roderick Warren, M.D. Eclectic Medical Institute, Cincinnati, 1882; mayor of Pekin, Ill., in 1887; a veteran of the Civil War; died at his home in Pekin, August 5, aged 74.

Charles Henry White, M.D. Harvard Medical School, Boston, 1862; rear admiral U. S. Navy (retired); died at his home in Center Sandwich, N. H., July 26, aged 76.

J. H. Dick (license, Kansas, 1901), a practitioner of Lawrence, Kans., for nearly forty years; died at his home August 6, from cerebral hemorrhage, aged 84.

Amable Aurez Laferriere, M.D. Ecole de Medicine et de Chirurgie, Montreal, 1868; died at his home in New Carlisle, Que., April 28, from arteriosclerosis, aged 67.

Bror Otto Ericson, M.D. Jefferson Medical College, Philadelphia, 1897; died at his home in Cassopolis, Mich., July 7, from inflammatory rheumatism, aged 48.

Dennis Francis O'Callaghan, M.D. Harvard Medical School, Boston, 1887; died at his home in Dorchester, Boston, July 29, from septicemia, aged 50.

Walter Frederick Appleton, M.D. New York Homeopathic Medical College, 1906; of Passaic, N. J.; died in White Haven, Pa., August 2, aged 35.

Frank Jones, M.D. University of Buffalo, N. Y., 1903; of Niagara Falls, N. Y.; died in Memorial Hospital, Niagara Falls, August 4, aged 38.

Albert Southworth, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1869; died at his home in Los Angeles, recently, from dysentery.

Thomas J. Smith, M.D. Cincinnati College of Medicine and Surgery, 1869; died at his home in Coshocton, Ohio, July 23, from gastritis, aged 67.

Charles H. Laas, M.D. University of Louisville, Ky., 1890; died at his home in Burton, Texas, August 4, from congestion of the brain, aged 49.

Solomon L. Reefy, M.D. Eclectic Medical Institute, Cincinnati, 1870; died at his home in Edinburg, Ill., August 2, from paralysis, aged 75.

Robert R. Church, M.D. University of Pennsylvania, Philadelphia, 1870; died at his home in Wormleysburg, Pa., July 30, aged 69.

Henry Marsh Haskell, M.D. Bellevue Hospital Medical College, 1878; died recently at his home in Redlands, Cal., aged 62.

William Wilford McMurdo, M.D. Washington University, St. Louis, 1905; died at his home in Marissa, Ill., August 6, aged 35.

Jerome E. Butler, M.D. University of Louisville, Ky., 1854; died at his home in Aspen Hill, Tenn., July 24, aged 83.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

ARTICLES ON SOCIALIZATION OF MEDICINE

To the Editor:—I am preparing a paper for the society on the "Socialization of Medicine." Please tell me where I can find something on the subject of medical work by contract or under state law in England, Germany, France or other countries, ancient or modern, where the state has taken a hand in such work. P. R. H., M.D., Nebraska.

ANSWER.—The following is a list of articles on this subject:

- A State Medical Service, London Letter, THE JOURNAL, Jan. 31, 1914, p. 391.
- Socialization of Medicine in England, Medical Economics, THE JOURNAL, Jan. 24, 1914, p. 316.
- Warbasse, J. P.: Socialization of Medicine, THE JOURNAL, July 18, 1914, p. 264.
- The Insurance Conflict, Berlin Letter, THE JOURNAL, Feb. 14, 1914, p. 549.
- Benefits of the British Insurance Act, Medical Economics, THE JOURNAL, July 26, 1913, p. 296.
- A New Form of Insurance in England, Medical Economics, THE JOURNAL, Jan. 23, 1909, p. 326.
- Medical Men: Their Place and Influence in the State, Brit. Med. Jour., Feb. 14, 1914.
- Industrial Insurance in Germany, Medical Economics, THE JOURNAL, March 28, 1914, p. 1039.
- Industrial Struggles of Physicians Abroad, Medical Economics, THE JOURNAL, Jan. 31, 1914, p. 398.
- The Place of Medical Men in the Modern State, Medical Economics, THE JOURNAL, April 4, 1914, p. 1112.
- Medical Remuneration under the Insurance Act, London Letter, THE JOURNAL, March 21, 1914, p. 945.
- Mr. Lloyd-George on the Insurance Act, London Letter, THE JOURNAL, March 7, 1914, p. 789.
- Carroll, J. B.: Workmen's Compensation Law and the Physician, Boston Med. and Surg. Jour., Jan. 1, 1914.
- French, J. R.: Medical Situation of New Workmen's Compensation Act, California State Jour. Med., April, 1914.
- Oliver, T.: Medico-Social Problems from an Insurance Point of View, Lancet, London, April 4, 1914.
- The National Insurance Act and Scarcity of Physicians, London Letter, THE JOURNAL, Jan. 17, 1914, p. 218.
- Rogers, B. M. H.: Experiences of Medical Adviser Under Insurance Act, Brit. Med. Jour., June 28, 1913.
- Rowntree, C.: Workmen's Compensation Act and Physician, Practitioner, London, August, 1913.
- Merrick, R. M.: Workmen's Compensation Act as it Affects Physicians, Boston Med. and Surg. Jour., Sept. 18, 1913.
- The Crisis in Germany, Current Comment, THE JOURNAL, Dec. 13, 1913, p. 2163.
- Medical Insurance Abroad, Medical Economics, THE JOURNAL, Dec. 27, 1913, p. 2314.

EFFECT OF LOSING TEMPORARY TEETH

To the Editor:—A patient of mine, a child of 4 years, has had the two upper central incisors knocked out. What, if any, is likely to be the effect on the growth of the jaw, and room for the other (permanent) teeth? The teeth were in perfect alignment before the accident.

WILLIAM H. GOODSON, M.D., Liberty, Mo.

ANSWER.—The accidental removal of the temporary teeth at the age of 4 should have no influence on the growth of the jaw, or on the development of the permanent teeth.

SOURCE OF ARMY ANTITYPHOID VACCINE

To the Editor:—Can you tell me what vaccine (from what laboratory) is used for antityphoid vaccination in the United States Army?

DR. RODGER-CHENOWETH, Escanaba, Mich.

ANSWER.—These vaccines are prepared in the laboratory of the Army Medical School at Washington, D. C. Vaccine from the same source is furnished for the navy and the organized militia as well as other departments of the government service, which call on the army laboratory for it.

BECK'S PASTE

To the Editor:—1. What is the formula for Beck's paste?
2. Is it indicated in treating intestinal fistula?

3. How is it used? C. C. COLLINS, M.D., Roachdale, Ind.

ANSWER.—1. Two forms of paste are used: (a) Bismuth subnitrate 30 parts and petrolatum 60 parts; mix and stir while boiling. (b) Subnitrate of bismuth 30 parts, white wax, 5 parts, soft paraffin 5 parts and petrolatum 60 parts; mix while boiling. One per cent. of solution of formaldehyd may be added to these pastes.

2. No.

3. The paste is sterilized before using. It is sucked up into the syringe while still liquid and cooled to the requisite temperature by running cold water over the syringe. It is injected very slowly and the injection is continued until the sense of pressure annoys the patient. Then the syringe is laid aside and a bit of gauze is held for a time over the outlet of the fistula to keep the paste from running out and an ice-bag is put over the region to harden the injected material.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ALBERTA: Edmonton, September 15. Registrar, Dr. Cecil E. Race, University of Alberta, Edmonton.

IOWA: Des Moines, September 10-12. Sec., Dr. Guilford H. Sumner, Capitol Bldg., Des Moines.

MISSOURI: Kansas City, September 28-30. Sec., Dr. J. A. B. Adcock, State House, Jefferson City.

NEW YORK: September 22-25. Chief of Examination Division, Mr. Harlan H. Horner, Department of Education, Albany.

Nevada May Report

Dr. Simeon L. Lee, secretary of the Nevada State Board of Medical Examiners, reports the written examination held at Carson City, May 4-6, 1914. The number of subjects examined in was 13; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 7, of whom 4 passed, including 1 osteopath, and 3 failed. Seven candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Kentucky School of Medicine		(1906)	77.2
Bellevue Hospital Medical College		(1888)	87.4
Royal University of Naples		(1903)	80.9

College	FAILED	Year Grad.
Kentucky School of Medicine		(1907)*
University of Maryland		(1384)†
Eclectic Medical Institute, Cincinnati		(1890)*

* Papers thrown out because of fraud.

† License not granted because of mental condition.

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
State University of Iowa, Coll. of Homeo. Med.	(1908)	Iowa
Tulane University of Louisiana	(1910)	Louisiana
Nebraska College of Medicine	(1907)	Utah
Jefferson Medical College	(1881)	Wisconsin
University of Pennsylvania	(1900)	Pa.
Western Pennsylvania Medical College	(1895)	Pa.

New Mexico April Report

Dr. W. E. Kaser, secretary of the New Mexico State Board of Health and Medical Examiners, reports the written examination held at Santa Fe, April 13-14, 1914. The number of subjects examined in was 13; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 5, all of whom passed. Eight candidates were licensed on satisfactory credentials. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Hering Medical College		(1904)	85.9
American Medical College, St. Louis		(1913)	75
Grant University, Medical Department		(1904)	82.3
University of Tennessee		(1913)	80.2
Royal University of Padua		(1886)	79.8

LICENSED ON CREDENTIALS

Atlanta Medical College		(1897)
Rush Medical College		(1913)
College of Physicians and Surgeons, Keokuk		(1875)
Omaha University, Medical Department		(1902)
Columbia University, Coll. of Phys. and Surgs.		(1904)
Hahnemann Med. College and Hospital, Philadelphia		(1892)
University of Pittsburgh		(1911)
Vanderbilt University		(1893)

Book Notices

HEALTH THROUGH DIET. A Practical Guide to the Uric Acid Free Diet Founded on Eighteen Years' Personal Experience. By Kenneth G. Haig, L.R.C.P., M.R.C.S., with the Advice and Assistance of Alexander Haig, M.A., M.D. Cloth. Price, \$1.25 net. Pp. 227. Philadelphia: J. B. Lippincott Company, 1914.

The importance of diet in securing and preserving health is not to be denied, and when we have a record of personal experience, the results deserve a patient hearing. The book comes to us with a certain handicap since we recognize that the author is thoroughly saturated with his father's peculiar ideas with reference to uric acid and its relation to disease. A glance at the contents soon shows that the term "Diet" is used in a special sense and means a "uric acid-free diet." The adoption of such a diet constitutes admission to a cult which has its stages from the first weaning from tea, coffee and soup, to the full renunciation in which every vestige of the hateful purins has been cast out. This cult uses ordinary terms with strange or exaggerated meanings. To talk of eggs, beans, peas, etc., as poisonous or as containing poison seems strange at first, but we soon learn that the essence of poisons is uric acid and everything which contains or can produce uric acid must at once be classed as poisonous among the initiated, although common people have been consuming such substances for ages without showing any ill effects. Then again, plain chemical terms become perverted in meaning in the dialect of the Haigites. "Cane-sugar is a stimulant by virtue of its acidity" (p. 30). What this may mean we cannot divine, but we believe that chemists still teach that pure cane-sugar is a perfectly neutral substance. Perhaps it may in some forms of metabolism give rise to acid products, but we are not aware that this is an ordinary action, unless forming carbon dioxide be recognized as constituting acidity. Again, we are told that "bread on the whole is not a very satisfactory food because it is very acid" (p. 23). It would appear that those saved from the horrors of uric acid have become so sensitive that they revolt at sour bread and we are sorry that England will not furnish them bread sweet enough to eat. The author has a new standard of nutrition, gauging the nutritive value of foods by their content of protein. Thus sugar, starch and butter or other fat are devoid of nutritive properties since they contain no protein.

The distinctness of view of those converted to the new way of life is shown by the following: "The chief argument against cheese as a food is that it is indigestible; from the meat eater's point of view this is so, but it does not hold for those on the Uric Acid-Free diet" (p. 15). The reader will also be interested in the following: "Peanuts, which are botanically not nuts at all, but pulses, are poisonous." "Bread made with baking-powder is certainly to be preferred to that made with yeast, which is poisonous." Lest the House of Haig be overlooked we find at intervals of about ten pages the title, publisher and author of "Some Recipes for the Uric Acid-Free Diet," by G. M. Haig.

The difficulties of the author and of other Haigites in a purin-eating world are enough to excite our sympathy. When venturing into profane society the author tells us that he usually takes some sustenance before leaving home "and then when I get there I eat what I can and play about with the rest, hiding the poisonous things under the knife and fork. This of course is not pleasant, but the matter has got to be faced out." A sad predicament indeed! A waterproof pocket in the dinner-coat to hold the "poison" would surely be handy. The author makes some comforting statements in regard to the effect of the new way of living which we gladly quote. "My temper certainly has been improved by being on Uric Acid-Free Diet." "Another small point is, that since I have been on Diet I have not been bothered by the unwelcome attentions of the flea, the midge, the mosquito and others of the kind. . . . This is a common experience amongst those on the Uric Acid-Free Diet." "Getting out of bed in the morning has no terrors for me and I find

the morning the best time for work." Dr. Haig still believes in cooking. He looks forward to an ideal diet consisting of fruit and nuts which will need no cooking, but in the times of imperfection in which we find ourselves he cannot dispense with the culinary art. As a scientific treatise, this book is valueless. As a specimen of the literature of a self-satisfied sect or fad it will prove interesting to any one who will take the trouble to read it.

MODERN ANESTHETICS. By J. Frederick Silk, M.D., Senior Anesthetist, King's College Hospital. Cloth. Price, \$1 net. Pp. 200, with 37 illustrations. New York: Longmans, Green & Co., 1914.

As the author says the principal object of this book is to describe in detail those procedures which he has found most useful in his own practice. The anesthetics most commonly used are briefly described, after which the technic to be followed and the difficulties most likely to occur are discussed. The choice of anesthetic in the judgment of the author should be the subject of a consultation between the surgeon, the medical adviser and the anesthetist. He gives his own views as derived from experience, but not in such a way as to be of great assistance to one in doubt. Silk gives little information in reference to the newer anesthetics, and particularly with reference to the use of alkaloids his advice is very indefinite. He is evidently carefully conservative, not wishing to discredit anything that may be of service, but placing the emphasis on those methods which his experience has shown him to be of tried worth. In indicating the principles to follow in choosing the anesthetic, he points out that the nature of the operation should have weight in determining which agent to employ. He states that although there is a general impression that children bear anesthetics well, there is a considerable mortality from this cause and that the number of children who escape by a slight margin is still greater. The technic of administration is fully described and the difficulties and dangers thoroughly considered. The later chapters of the book discuss operations on special regions and the methods of spinal and local anesthesia and analgesia. The author cannot be said to be optimistic for local methods, although he admits that they are especially appropriate in the operations on the eye and the nasal mucous membrane. The anoci-association method of Crile is given in Crile's own words. The brief comments made on the method are favorable.

A MANUAL OF CLINICAL DIAGNOSIS BY MEANS OF LABORATORY METHODS FOR STUDENTS, HOSPITAL PHYSICIANS AND PRACTITIONERS. By Charles E. Simon, B.A., M.D., Professor of Clinical Pathology at the College of Physicians and Surgeons. Eighth Edition. Cloth. Price, \$5 net. Pp. 802, with 210 illustrations. Philadelphia: Lea & Febiger, 1914.

In this edition, Simon has included, among other additions, a discussion of the important serodiagnostic tests of Abderhalden based on the appearance of the "protective ferments" in the blood-serum; the applicability of the complement-fixation test to latent gonorrheal infections, and the phenolsulphonephthalein test for renal activity. The subject-matter of the book is divided into two parts. The first is devoted to technical questions and the second to the application of laboratory findings to diagnosis. This is an excellent arrangement, as any one who has had experience with students in this subject will agree. The tests discussed throughout the work, are for the most part, very satisfactory and may be accepted as the best for the matter in hand. Halin's newer methods of studying the various nitrogen factors of the blood have been wisely included. It is noted that Simon prefers the Noguchi acetone-insoluble lipoid antigen for the Wassermann reaction, although he states that he is about to employ the cholesterolized alcoholic extracts in his work. The latter antigens are, in our opinion, the best at our disposal. No mention is made of Benedict's qualitative test for sugar in the urine, which test is probably the most satisfactory one for routine purposes. Further, we are able to find no reference to the formaldehyd-titration method for ammonia and amino-acids or to Lange's colloidal gold test of the cerebrospinal fluid. Both of these tests would seem to be of sufficient value to warrant inclusion. This work is

to be recommended to all who may desire a thoroughly reliable and up-to-date treatise on clinical diagnosis. The discussions are clear and exact. The selections of methods are entirely adequate. The illustrations are good and the color plates especially worthy of mention.

THE PRINCIPLES AND PRACTICE OF GYNECOLOGY. For Students and Practitioners. By E. C. Dudley, A.M., M.D., Professor of Gynecology, Northwestern University Medical School. Sixth Edition. Cloth. Price, \$5 net. Pp. 795, with 463 illustrations. Philadelphia: Lea & Febiger, 1913.

There are few medical text-books in this country that for so many years have been regarded as standard as has this one of Dudley. In 1902 the present reviewer wrote, "Dudley's book has always been held in high esteem both by the specialist and by the general practitioner who is compelled to do a certain amount of gynecologic work, and this edition will, we are sure, make it still more popular." This was written twelve years ago in reviewing the third edition; it was then an old and well-known text-book. The popularity of Dudley's Gynecology rests, primarily, on the fact that the subject-matter is presented in a practical manner with sufficient elementary details to satisfy the general man, but not so much as to offend the specialist; and, secondarily, on the fact that the book is liberally and beautifully illustrated with what surely may be regarded as practical and useful illustrations. The sixth edition has been brought up to date in every particular. There is scarcely a chapter that does not bear evidence of revision. Many large illustrations have been added, making the book better than before in this regard at least. In a word, this book may be regarded as a standard text-book representing modern gynecology.

DEVELOPMENT AND ANATOMY OF THE NASAL ACCESSORY SINUSES IN MAN. Observations based on Two Hundred and Ninety Lateral Nasal Walls, Showing the Various Stages and Types of Development of the Accessory Sinus Areas from the Sixtieth Day of Fetal Life to Advanced Maturity. By Warren B. Davis, M.D., Assistant Demonstrator of Anatomy in the Daniel Baugh Institute of Anatomy, Philadelphia. Cloth. Price, \$3.50 net. Pp. 172, with 57 illustrations. Philadelphia: W. B. Saunders Company, 1914.

This book is mechanically excellent. It contains fifty-seven slightly tinted accurate and very clear cuts illustrating the nasal accessory sinuses at all stages from embryonic to adult life. The legends explaining the various figures are satisfactory, so that anatomic features may be taken in quickly. The text is clear and concise, yet comprehensive, and all in all it is a valuable addition to the literature of the development and anatomy of the region specially interesting to the rhinologist.

PLAIN RULES FOR THE USE OF TUBERCULIN. By R. Allan Bennett, M.B., Physician in Charge of Devon County Council Tuberculosis Dispensary. Cloth. Price, \$1 net. Pp. 48. New York: William Wood & Co., 1914.

This small book containing twenty pages of useful text gives plain and conservative directions as to the technic and indications for tuberculin treatment. It is by no means exhaustive, but it may be said to be reliable. The author opposes the system by which general reactions are allowed to occur, but thinks that for working people the plan of procedure that avoids all reactions consumes too much time. Hence he aims to graduate the doses so that while focal reactions may occur, the general reactions are avoided. In his estimate of the relative value of the methods, he puts the combination of sanatorium and tuberculin first, sanatorium alone second, and tuberculin third.

BLACK'S MEDICAL DICTIONARY. By John D. Comrie, M.A., B.Sc., M.D., Lecturer on History of Medicine, University of Edinburgh. Fifth Edition. Cloth. Price, \$2.50. Pp. 858, with 353 illustrations. New York: The Macmillan Company, 1914.

This is an encyclopedic, one-volume dictionary intended for the use of lay persons who wish an explanation of medical terms and conditions in non-technical language. The text has been thoroughly revised and is well up-to-date. So far as a brief examination indicates, the work fulfils its purposes satisfactorily.

Miscellany

One Standard of Entry to the Practice of the Healing Art

The following statements, made by Dr. F. M. Crandall of New York a few years ago in regard to the various systems of drugless therapy, apply with equal force to-day. The followers of some of these "systems" are persistent in their efforts to lower educational standards or break down the requirements of medical practice acts in order that they can enter on the practice of the healing art without having to comply with the educational requirements or to present the qualifications which are deemed necessary for all other practitioners. There should be no special privileges granted to any "system." The people of every state have a right to insist that only properly qualified persons are given the legal right to treat human ailments.

"The most strenuous work of recent years has consisted of opposition to the demands of various systems of pseudo-medicine. These systems are nothing more or less than levers and sledge hammers seized upon as the most effective means of breaking through the medical laws. And here we come upon a subject upon which there is much misapprehension. The medical laws are but a part of the general educational laws of the state. These laws are wide in their application, and cover many professions and diverse conditions. There is nothing exceptional in the laws covering medical practice. They are at the farthest possible remove from class legislation. They are simply a part of the great educational system of the state. The medical profession has upheld the hands of the state educational authorities, whose aim has been to enact a broad and consistent system of just and equitable laws. A state educational system has, therefore, been built up, of which the laws controlling medical practice are an integral part.

"POSITION OF THE MEDICAL PROFESSION

"The position of the medical profession is often misunderstood and their arguments have frequently been misjudged. The opposition of physicians to attempts to destroy the medical laws is often attributed to a spirit of trade unionism. This is controverted by the single fact that no attempt is made by the profession to curtail the practice of medicine by competent men. It is one of the fundamental principles that every man and woman exhibiting proper qualifications should be admitted to practice. Our opposition to pseudomedicine is, and should be, educational, not professional. We do not try to raise barriers against practitioners because they use a special system or adopt certain remedial measures. We do not oppose certain prevalent isms because of their methods of treatment, but because they are new and very clever manifestations of the old, old scheme to get within the medical fold without expending the time and money necessary to make a competent practitioner. The various systems of pseudomedicine are not pushed forward year after year with such determination because men so love this or that particular form of treatment, but because they offer the most promising means of evading the requirements of preliminary education, four expensive years in the medical college, a state examination, and then, perhaps, two years of unpaid service in a hospital. It is the educational question that is at the bottom of every one of these modern isms, and they are the more aggressive as the educational barriers are raised higher. It is upon educational, not professional grounds that we oppose them.

"TREAT ALL ALIKE; NO SPECIAL FAVORS

"The medical profession approves the system which requires the same general professional education of all its members. The specialist upon the eye and the specialist upon the throat, the physician and the surgeon, must each undergo the same training and must pass the same state examination. One may select any specialty he chooses and may adopt any method of treatment which his educated judgment dictates. He may use large doses or small, massage or electricity. What the state requires for one body of practitioners it should not abate in favor of another.

"AN ADEQUATE TRAINING REQUIRED

"We have one sound reason for opposing these systems which permit an abbreviated education, and one argument that no man can gainsay. We may properly demand that

every man and woman who enters upon the practice of the healing art should have adequate education. Here we are on ground that cannot be misjudged or misrepresented. We ask no favors or special privileges. We are not the ones who are seeking to bring half-educated practitioners in by the back door. We simply ask equal requirements for all. Our position is, that those who seek to treat disease should go in through the same door, and a few should not be permitted to crawl in through holes and underground passages. We simply ask for an American square deal and equal rights for all."—*New York and Philadelphia Med. Jour.*, reprint *Jour. Med. Soc. New Jersey*, January, 1906, p. 247.

The Supposed Experimental Production of Hemolymph Nodes and Accessory Spleens

Owing to the conflicting evidence at hand concerning the production of accessory spleens and hemolymph glands *de novo* or from lymph-nodes, Arthur William Meyer (*Jour. Exper. Zool.*, 1914, xvi, 241) has made further experimental investigation of this important subject. It has been customary to classify the lymph-glands as hemolymph nodes and ordinary lymph-glands. Both types of glands or nodes have been supposed to occur in man, monkeys, rodents, domestic animals, birds and fishes. Those who attempted this study found that between these two types of lymph-nodes neither gross nor microscopic differentiation was possible. No definite characteristics could be assigned to either class, because the observer thought that all forms of transition existed. In spite of this acknowledged difficulty of differentiation, Levoe and Warthin formulated elaborate classifications, and men such as Tizzoni, Ethernod and others have described splenic nodules, on the peritoneum and on the great omentum, which they regarded as the result of physiologic compensation for the inactivity of the main spleen. On this supposition Tizzoni performed several splenectomies on dogs with the hope of proving his conclusion. He recorded no controls and gave no details regarding these dogs, such as their age, weight, or the size and position of the accessory spleens which he described. Foa and Luschka have already pointed out that the so-called accessory spleens are found also in the presence of a normal spleen. Of the thirty splenectomies which Mosler performed, the great omentum of only one dog was covered with dark-red nodules. Even granting that these were accessory spleens there is no proof that they were found as the result of splenectomy.

Meyer's experiments were carried out on dogs from two litters of five each. He performed splenectomies on eight, keeping one dog from each litter for a control. At the time of the operation they were examined for hemal nodes, and only one node was found with a reddened center in the gastrosplenic omentum. At the time of necropsy, from thirty to 126 days after operation, neither accessory spleen or hemolymph nodes were found, and all of the lymph-glands in the splenectomized dogs were normal, except in two dogs in which the bronchial lymph-nodes were intensely red. These nodes were injected and the afferent trunks were plainly visible up to the lung, which they entered, while the efferent trunks joined the larger mediastinal vessels near the jugulosubclavian junction. Furthermore, he examined seventy dogs and approximately one hundred cats, selected at random. Those nodes which were under suspicion were taken from the animals, examined microscopically and found to be normal lymph-nodes of the ordinary type.

Further experiments were made on five guinea-pigs of known weight. Guinea-Pig 1 was given injections of distilled water; Guinea-Pig 2 of oxalic acid, and Guinea-Pigs 3, 4 and 5 injections of diphtheria toxin. One hemolymph node was found in both 4 and 5; but since Retterer has shown that the reddish lymph-nodes occur in normal guinea-pigs, of all ages and under all conditions, Meyer is forced to conclude that the foregoing results are not necessarily due to his experiments. These reddened nodes were injected and found to maintain their previous connection with the lymphatic system.

It has long been known that changes in the lymph-nodes occur following various pathologic conditions, and that they

also remain unchanged and are not converted into another organ with a different function, losing their connection with the lymphatic system.

Investigation of animals subjected to bleeding has brought the same results. From these experiments Meyer concludes that the injection of toxins, bleeding or the removal of the spleen fails to produce any change of lymph-nodes into hemal nodes, thereby disproving Tizzoni's experiments which have been accepted for decades.

Some Mortality Statistics

The present population of the United States is not far from 100,000,000. The number of persons of both sexes, aged 70 and over, in 1910 was 2,270,021. According to the latest English life tables, out of every million born 277,351, or 27.7 per cent., may normally expect to reach the age of three-score and ten. In the United States the annual number of births is about 2,500,000, and the annual number of deaths is about 1,350,000. Of those who died during 1912, approximately 236,500, or 17.6 per cent., had lived less than one year, and 329,400, or 24.4 per cent., had lived less than five years.

The principal causes of death are as follows: first, tuberculosis, which affects every period of life and causes in the aggregate about 154,000 deaths; second, heart diseases, also affecting every period of life, but chiefly persons over 40, causing a mortality of about 150,000; third, nervous diseases, which account for about 138,000 deaths; fourth, pneumonia (all forms), about 132,000; fifth, intestinal diseases, about 123,000; and sixth, genito-urinary diseases, about 111,000. Following these six, in the order of importance, are accidents, causing about 182,000 deaths, and tumors, malignant and benign, about 75,000. These eight groups of cases combined account for about 72 per cent. of the aggregate mortality of the United States, which, as previously stated, is approximately 1,350,000 per annum. Other important causes are typhoid fever, the mortality from which is about 20,000 per annum; suicides, numbering approximately 16,000; deaths from parturition, about 15,000, and homicides, 6,000 to 7,000.

This may be considered the normal mortality of a civilized country not subject to exceptional or uncontrollable mortality conditions, such, for illustration, as continue to affect a great country like India even at the present time. The death-rate of the registration area of the United States during 1912 was only 13.9 per thousand, against a death-rate of 32 for British India. Of the 7,500,000 deaths, in round numbers, during the year 1911, 354,000 were caused by cholera, 58,000 by small-pox, 733,000 by plague, and 4,200,000 by fevers. Most of these causes are no longer an affliction of modern civilized countries, and they are fortunately brought slowly under control in the Indian Empire, where the death-rate has gradually been reduced from extraordinary proportions to a rate not much above the normal for the large cities of this country fifty years ago. The best illustration of India's marvelous sanitary progress is to be found in the reduction of the death-rate of the European army during recent years. Military discipline and conformity to sanitary rules and regulations, no doubt, largely account for this reduction, which has been of immeasurable benefit, not only to the European, but also to the native population.—The Chances of Death and the Ministry of Health, by Frederick S. Hoffman, Yale address.

Hints to Authors

1. Make your articles as short as is compatible with a clear expression of your facts or ideas. Many an article is not read because it is so long; or else its point is smothered in verbosity.

2. Leave Hippocrates and the other ancients undisturbed. They should rest now.

3. Do not spoil your work with a lot of quotations from foreign authors. Refer to them, if you must, in a footnote.

4. Have your paper typewritten and with wide-spaced lines; and,

5. Keep a copy.—*South. Med. Jour.*

Medicolegal

Liability for Operations Performed without Consent in Charitable Hospitals

(*Schloendorff vs. Society of New York Hospital (N. Y.), 105 N. E. R. 92*)

The Court of Appeals of New York affirms a judgment for the defendant hospital in this action wherein the plaintiff sued for damages alleged to have been sustained from an operation alleged to have been performed on her in the defendant hospital without her consent. The court says that, taking the plaintiff's version of the case, she went to the hospital suffering from some disorder of the stomach, and later consented to an examination under ether in order that the character of a lump which had been discovered might be determined, but that there must be no operation; yet, while she was unconscious, a tumor was removed. Her testimony was that this was done without her consent or knowledge, although that was sharply contradicted. Following the operation, and, according to the testimony of her witnesses, because of it, gangrene developed in her left arm, some of her fingers had to be amputated, and her sufferings were intense.

The Court says that every human being of adult years and sound mind has a right to determine what shall be done with his own body; and a surgeon who performs an operation without his patient's consent commits an assault, for which he is liable in damages. This is true, except in cases of emergency when the patient is unconscious, and when it is necessary to operate before consent can be obtained.

The fact that the wrong complained of here was trespass, rather than negligence, distinguished this case from most of the cases that have preceded it. In such circumstances the hospital's exemption from liability could hardly rest on implied waiver. Relative to this transaction, the plaintiff was a stranger. She had never consented to become a patient for any purpose other than an examination under ether. She had never waived the right to recover damages for any wrong resulting from this operation, for she had forbidden the operation. In this situation, the true ground for the defendant's exemption from liability was that the relation between a hospital and its physicians is not that of master and servant. The hospital does not undertake to act through them, but merely to procure them to act on their own responsibility. The wrong was not that of the hospital; it was that of physicians, who were not the hospital's servants, but were pursuing an independent calling, a profession sanctioned by a solemn oath, and safeguarded by stringent penalties. If, in serving their patient, they violated her commands, the responsibility was not the hospital's; it was theirs. There is no distinction in that respect between the visiting and the resident physicians. Whether the hospital undertakes to procure a physician from afar, or to have one on the spot, its liability remains the same.

It is also true of nurses, as of physicians, that, in treating a patient, they are not acting as the servants of the hospital. The hospital undertakes to procure for the patient the services of a nurse. It does not undertake, through the agency of nurses, to render those services itself. Whatever the nurse does in the preliminary stages is done, not as the servant of the hospital, but in the course of the treatment of the patient, as the delegate of the surgeon to whose orders she is subject. The hospital is not chargeable with her knowledge that the operation is improper, any more than with the surgeon's.

Waivers of Privilege

(*State vs. Long (Mo.), 165 S. W. R. 748*)

The Supreme Court of Missouri says that it concedes the statute of privilege to be a wise one, but it should never be so construed as to make it both a shield and a dagger at one and the same time. If the patient is suffering from a malady, the physicians should not be allowed first to bring to light that affliction of the patient. The very purpose of the statu-

is to hide, as with a veil, the malady and trouble for which the physician treated her, and what may have passed between them in the confidential relationship of physician and patient. But when the veil has been lifted by the patient, or with her consent, and the secrets of the sick chamber are given to the world, what logic is there in saying that the patient can clog the wheels of justice itself, by closing the mouth of other physicians, who know the real facts? In other words, if the patient raises, or permits to be raised, the veil of secrecy, with lying lips as to what the conditions were, should this waiver of secrecy still leave to her the power of suppressing the truth, by objecting to other physicians who about the same time treated her for the same alleged trouble? The court thinks not. In other words, if a patient is suffering from a given malady, and is treated by several physicians near the same time, for the same trouble or malady, then if she and one of her physicians with her consent make public the character of her trouble, she has waived the right longer to keep the exact character of that trouble secret, and the other physicians are competent to testify as to what this malady or trouble was in reality. Any other rule would be but to permit a patient in a court of justice to play both fast and loose.

So, if a patient is injured in a railway wreck and calls several physicians in the course of a reasonable time to treat him for such injuries, changing at times from one to another, but all treating him for the selfsame trouble, then if the patient breaks the secrecy by permitting one to testify as to the character of his injury, it is broken as to all. Any other construction of the doctrine of waiver (a doctrine thoroughly recognized in this state) would permit the patient to continue to employ physicians until he got one to his choosing, and, when he did so, could make him the sole agent to make public the secret of the sick-room. Such a course would be an abhorrent fraud on the courts, and one for which they should not stand. Justice should not be trifled with in any such manner. And, if privilege is once waived, it remains waived until the determination of the case, it matters not how many trials may be required.

Emergency Requirements for Injured Railway Employees

(*Tifpecanoe Loan & Trust Co., administrator, vs. Cleveland, Cincinnati, Chicago & St. Louis Railway Co. (Ind.)*, 104 N. E. R. 866)

The Appellate Court of Indiana, Division No. 1, says that if an employee of a railway company is injured as a result of hazards to which his employment exposes him, and, if his injuries are of such a nature as to render him incapable of caring for himself, it becomes the duty of the company to take such steps as are reasonably necessary and proper, under the circumstances, to prevent an aggravation of the injury through exposure, or for the want of medical or surgical assistance. Under such circumstances, if the servants of the company knowingly leave such injured person to die of exposure, or to bleed to death from his wounds, a legal responsibility for such consequences will be imposed on the company; and, if they take him into their custody, they must exercise reasonable care in the treatment accorded him. Under such circumstances the common instincts of humanity require that the helpless injured person should be taken in charge and removed to a place of safety, and that, if necessary, medical or surgical aid should be provided. This duty has been recognized by the Supreme Court of this state as one which arises in extraordinary cases in which medical or surgical assistance is imperatively required to save life, or to prevent further serious bodily injury. It is said that the duty arises with the emergency, and with it expires. In this case a section-hand in the employ of the defendant had his leg broken and severely cut, and was rendered unconscious and incapable of taking care of himself. There were some averments in the complaint to the effect that the company's physician, who was the first to treat the injured man, was negligent in failing to disinfect the wound, and to remove the gravel, sand, cinders, and other foreign substances from the wound, and that as a result blood poisoning

ensued, which resulted finally in death. It is well settled in Indiana, however, that a railway company cannot be held liable for damages resulting to one of its injured employees as the result of the negligence of a surgeon called by the company to render surgical aid to such employee. Therefore, as the complaint did not aver that the defendant or its agents were negligent in selecting and employing an unskilled or incompetent surgeon, the defendant could not be held liable for the negligence or unskillfulness of the surgeon whom it called.

- 10 Atypical Modes of Onset in Dementia Praecox. S. N. Clark, Kankakee, Ill.

2. What is Paranoia?—Unless one uses the word merely in a symptomatic or descriptive sense (in which case it is an unnecessary synonym for the old delusional insanity), Abbot says, paranoia is a psychosis, but not a disease process. It is neither a pure affect-psychosis nor a pure ideation-psychosis, but rather a combined associational affect-ideation-psychosis. It is a continuous self-perpetuating faulty association of ideas and affects without disturbance of the thinking or affective or conative processes of such. It is purely functional, but not related to the manic-depressive or dementia praecox psychoses, which are ordinarily, though to his mind wrongly, called functional. Hence it does not lead to dementia, except in the line of its own evolution and it does not necessarily have any of the symptoms of the other psychoses except delusions, which may occur in all of them. Its mechanism is that of prejudice but the basal complexes involved are very intimate and personal ones with correspondingly strong and durable affects. This conception gives some therapeutic hope, realized by Abbot in at least one case.

5. Are Dementing Psychoses Increasing?—Bancroft feels that while it is demonstrably certain that paresis has increased during the last twenty-five years, it is by no means equally certain that an actual increase in the other dementing

psychoses has occurred. Fundamental conditions are much the same now as they were fifty years ago. With the exception of parasymphilitic brain conditions the actual disparity between the functional diseases of the mind and the dementing psychoses is probably not much greater now than formerly, making due allowance for increase in population. Certain prophylactic endeavor is suggested by this cursory survey. Curtailment of the immigration of mental defectives at the source, restriction of alcoholic indulgence, prevention of syphilitic infection, stricter segregation of the feeble-minded, greater intelligence in entering on the marriage relation. Bancroft suggests, are some of the steps by which a decrease among the dementing psychoses may be attained.

7. Brain Atrophy in Relation to Insanity.—The more important results of Rosanoff's analysis are: The index of atrophy seems to vary somewhat with age, showing increase as age advances. The index to atrophy seems also to vary with the state of nutrition, though not so clearly, showing apparently some increase in cases of emaciation. In cases of insanity the index of atrophy varies with the clinical group; it is greatest in cerebral arteriosclerosis; it is greater in general paresis and in senile dementia than in dementia praecox.

There is close correlation between degree of mental deterioration observed clinically and index of atrophy determined at autopsy: that is to say, mental deterioration, of whatever nature, goes hand in hand with brain atrophy. There is close correlation between duration of the deteriorating psychosis and index of atrophy. Inasmuch as interest will naturally center on dementia praecox, rather than on psychoses occurring on a basis of coarser and better understood brain lesions, a special analysis of the data pertaining to that group has been undertaken with a view to determining the share of the atrophy which is in that connection to be attributed to senility or to emaciation. This analysis has shown Rosanoff that if senile involution plays any part in the production of brain atrophy in dementia praecox, that part is but a slight one; the bulk of the atrophy is not due to it. The analysis has also shown that emaciation, like senile involution, plays but an unimportant part, if any, in the production of brain atrophy in dementia praecox; the bulk of the atrophy is not due to it. The conclusion is therefore drawn by Rosanoff that dementia praecox is associated in some way with changes in the brain which lead to atrophy.

8. Similar and Dissimilar Psychoses in Relatives.—Ricksher found that similar psychoses occur in about 50 per cent. of parents and children, and in brothers and sisters occur in about 66 per cent. of the cases. The age of onset of the psychosis as a rule is earlier in the child than in the parent. When the father and daughter or mother and son each suffer from dementia praecox the difference in the age of onset is most marked. Idiot children are not found as often as children with less severe mental disorders. Epilepsy in their cases was transmitted through the fathers to the sons. The transmission from mother to child is only a very little more frequent than from father to child. Similar psychoses occur in brothers and sisters in about 66 per cent. of cases. Dementia praecox is the most frequent psychosis found in brothers and sisters and is the psychoses most frequently found in one child when the brother or sister suffers from some other mental disorder. Mental disease is more apt to appear earlier in sisters than in brothers, except that when dementia praecox is found in one child and manic-depressive insanity in the other the average of onset is less in the brother than in the sister whether the brother suffers from manic-depressive insanity or from dementia praecox. Family histories and the type of psychoses in other insane relatives are not obtainable and definite conclusions regarding the effects of insanity in relatives on the production of dissimilar psychoses in the child cannot be drawn.

14. Schick Reaction.—The results of immunizing injections and laboratory experience in testing the blood for antitoxin have shown that only those individuals contract diphtheria who have no antitoxin or only a minute amount in their blood and tissues. The methods previously in use for estimating antitoxin, and thus separating the susceptible from the non-susceptible individuals, have been too troublesome to be of practical value in routine cases. Schick recently published a simple clinical test by which this can be accomplished. The reaction depends on the local irritant action of minute quantities of diphtheria toxin when injected intracutaneously. If antitoxin is absent, or present only in very small amounts, insufficient for protection, a positive reaction will appear in twenty-four to forty-eight hours. This is characterized by a circumscribed area of redness and slight infiltration which measures from 1 to 2 cm. in diameter. It persists for seven to ten days, and on fading shows superficial scaling and a persistent brownish pigmentation. The amount of toxin injected as advised by Schick is 1/50 MLD for the guinea-pig in 0.1 c.c. of normal saline. The authors prefer 1/50 MLD in 0.2 c.c.

The Schick reaction was carried out by them during the past six months on all patients entering the scarlet-fever pavilion of the Willard Parker Hospital. In all, 700 patients were thus tested, and of these, 400, or 57 per cent., gave negative reactions. Only cases giving positive reactions were immunized; those giving a negative reaction received no immunization, but were carefully observed. Although more than a quarter of the negatively reacting patients became bacillus carriers during their stay in the wards, no cases of clinical diphtheria developed among them. The remaining 300 patients who gave positive reactions received in practically all cases some form of toxin-antitoxin mixture. Among those who reacted insufficiently to the attempt at active immunization with toxin-antitoxin mixtures, 42 developed clinical diphtheria; of these, 20 were nasal, 20 tonsillar and 2 laryngeal diphtheria. The great majority of the cases were of a mild type. The percentage of individuals susceptible to diphtheria is greatest between the ages of 1 and 4 years. It is less during the second six months of life and less in older children and in adults.

15. Treatment of Recurrent Sibilant Bronchitis.—Rachford calls attention to the clinical fact that (1) recurrent rhinitis and recurrent sibilant bronchitis, which are sometimes associated with rather severe asthmatic attacks, and almost always with a severe paroxysmal cough, are very commonly caused by some kind of food intoxication; (2) that recurrent attacks of rhinitis and whistling bronchitis, which is one of the most common symptom groups the physician is called on to treat, may be in most instances almost or quite relieved by dietetic treatment. He insists that this symptom group occurs not infrequently in children who have a predisposition to migraine, recurrent vomiting and urticaria.

During the attack sweets, butter fats, eggs and raw fruits are especially to be avoided. Strawberries, rhubarb, tomatoes, salads, shell-fish, tea, coffee, pastry, gravies, cream, cod-liver oil and alcohol are excluded from the diet. Saccharin is to be used instead of sugar. Skimmed milk may be allowed. The following foods may be allowed: beef, mut-

ton, fowl and fish in moderation, cereals, bread, all vegetables not above prescribed, cooked fruits, skimmed milk and thick soup.

About two months after the patient has recovered from the attack the above diet may be carefully modified by adding one egg a day to the diet, then perhaps two weeks later, milk containing 4 per cent. fat may be substituted for skimmed milk. Some few weeks later all raw fruits, oranges excepted, may be added to the diet. Some weeks later, small quantities of sugar may be used for sweetening cereals and stewed fruits. After five or six months the child may return to his original diet, with the exception that he must eat sparingly of sweets and must eat nothing between meals. If the symptom-group returns on the addition of any article of diet, that particular food is to be permanently excluded from the diet.

During the attack the patient is to have all the outdoor air he can get with as little exercise as possible. As he recovers from his attack, exercise in the open air is advisable. During the attack, constipation should be relieved by some of the magnesium salts. Milk of magnesia or calcined magnesia are especially suitable for this purpose. Magnesium sulphate may be used in small doses in older children. Alkalies in the form of sodium bicarbonate, potassium bicarbonate or potassium citrate should be given in fair-sized doses, 5-grain capsules three or four times a day. In younger children who object to the taste of sodium bicarbonate direct the mother to distribute through the child's food a teaspoonful of this salt each day. Tincture of belladonna should be given for a short time in 2 to 4 minim doses three times a day. If constipation cannot be controlled by diet some form of cascara or other palatable laxative should be used as indicated. The belladonna is discontinued, but an alkali in some form should be given for six to eight weeks. Sodium bicarbonate is the best alkali for this purpose and may be given in moderate-sized doses once or twice a day.

24. **Involution of Uterus and Effect on Nitrogen Output of Urine.**—As the results of Slemmons' investigations, it is apparent that the process of involution causes a rise in the urinary nitrogen and that the amount of excessive elimination corresponds to the nitrogenous content of the non-involved uterus. His observations offer confirmatory evidence of this fact from three points of view: First, by the comparison of the puerperal and postpuerperal periods when the uterus has not been removed; second, from the comparison of the aggregate excretion in cases in which the uterus was removed and in which it was not; and third, from the comparison of the actual daily difference in such cases with the theoretical amount of nitrogen which would be expected as a result of the involutionary process. Slemmons, therefore, concludes that waste products from the involuting uterus pass into the circulation, are excreted by the kidneys, and in some measure throw additional work on these organs during the early part of the puerperium.

It does not follow, however, that the diet should be restricted in the puerperium. On the contrary, Slemmons'

observations indicate that the increase in the excretion of nitrogen is not large enough to require such restriction, provided the patient is normal. If any therapeutic inference may be drawn, it is in the nature of a justification of the present-day tendency to allow a generous diet to recently delivered women. On the other hand, in patients suffering from toxemia of pregnancy, the additional work which the kidneys must perform in the puerperium does become a matter of practical importance. In such circumstances these organs should be given the fullest opportunity to recover from the strain to which they have been subjected, and, with this end in view, the diet should be limited. Such precaution is necessary not only because the renal cells have been damaged, but also because an excretory capacity somewhat greater than normal is desirable. The inspection of the urine-chart of a convalescent eclamptic teaches that in the days immediately following delivery the kidneys are eliminating an unusually large amount of waste products, even though the consumption of food is small. Formerly, the large nitrogenous excretion in such cases was attributed to the elimination of waste material which had previously been retained, and whose retention had caused the toxemia. Such a view is evidently incorrect, as Slemmons' observations show that the large excretion of nitrogen in these, as well as in normal cases, is due to the involution of the uterus.

25. **Diastatic Ferment in Feces in Certain Diseases of Pancreas.**—From Brown's study on the diastase content of feces in normal and in certain pathologic conditions the following conclusions are drawn: The stool, if a rigorously exact method is carried out as to food, purgative employed, preservation of specimen, estimation of ferment, etc., furnishes a diastase content within definite limits. The effect of waiting too long after the stool has been obtained before making the examination, the influence of variations in temperature in the place in which it is kept, and of different laxatives and different foods, is so great as to render results obtained by methods in which insistence on such a rigorous technic has not been made of much less value.

Extensive carcinoma of the pancreas showed no diastase in the tube of lowest dilution in Brown's method, and this absence of ferment should prove of great help in the diagnosis of this condition. In chronic pancreatitis diastase was present in the stool, but in markedly diminished amounts. In achylia gastrica the diastase content of the stool was practically normal in all the cases examined. This, in the first place, suggests that in the absence of hydrochloric acid some other method of pancreas activation is called into play, and, in the second place, that the diarrhea met with in certain of these cases of achylia gastrica—the so-called gastrogenous diarrhea—is not of pancreatic origin.

26. **Peripheral Origin of Surgical Shock.**—Mann found it impossible to reduce the anesthetized animal to a state of shock by any degree of sensory stimulation, provided all hemorrhage is prevented and its abdomen is not opened. He has been unable to show that acapnia is a primary factor in the production of shock. Shock is not due to disturbance of the respiration, but the respiratory center is more quickly injured than any other vital center by shock. The vasomotor center is not depressed nor fatigued in shock. It is the most resistant of all the vital centers. The peripheral and untraumatized visceral arteries are constricted in shock. Shock is not due to primary failure of the heart nor to involvement of the cardio-inhibitory or cardio-accelerator mechanism. It is possible to produce the signs of shock by the use of excessive heat or cold. The easiest and most certain method of producing shock is by exposure and traumatization of the abdominal viscera. This, judging from the literature, has been the method used by nearly all investigators of shock. Shock produced by exposure and trauma of the abdominal viscera is not due alone to a paralysis of the vasomotor mechanism of the splanchnic area.

The cause of shock, Mann says, is the tremendous loss of red cells and fluid from the blood, due to the reaction of the great delicate vascular splanchnic area to irritation—an acute inflammation of the peritoneum, due to trauma and

exposure to the air and changes of temperature. The great amount of this loss is apparent when it is taken into consideration that the peritoneum has an extent as great as the entire cutaneous surface of the body. The factors involved in their reaction to irritation are the same as those involved in any other local inflammatory process, and certainly do not involve the nervous system to any greater extent. The profound general effect is due to the actual loss of red cells and fluid from the circulating blood through stasis, diapedesis, exudate, endothelial changes, etc. In the course of operations in which the abdomen has not been opened, a loss of fluid and cells from the blood occurs. But the loss is, except when great areas of subcutaneous tissue have been exposed, comparatively unimportant.

Certain accessory factors which help to produce the condition of shock are muscular relaxation, decrease in intra-abdominal pressure and impaired respirations, all of which tend to decrease the amount of blood returned to the heart. The effect of chilling and the use of hot applications should be considered. Degenerative changes in the cells of the central nervous system are the result and not the cause of shock. General anesthesia of moderate depth prevents painful impulses from affecting the nerve cells of the central nervous system. Nerve blocking under such conditions is useless, so far as the prevention of shock is concerned. A relatively slight decrease in blood-supply may be sufficient to depress markedly the cells of the cerebral cortex. Care should therefore be taken to exclude this factor before ascribing such depression to inhibition.

Mann is of opinion that the use of word "shock" should be avoided, and instead an accurate and detailed description of the patient's condition should be given. If the term be used at all it should be applied to the condition in which, without any grossly discernible hemorrhage having occurred, the amount of circulatory fluid is greatly diminished on account of stagnation of the blood in the smaller veins and capillaries or by exudation of the fluid and cellular elements of the blood from the same.

38. **Coccidioidal Granuloma.**—Coccidioidal granuloma, according to MacNeal and Taylor, is a very definite specific infectious disease, subacute or chronic, and tending to a fatal issue. Twenty-four cases have been recognized in various parts of the western hemisphere, most of them in California. The disease has been observed almost exclusively in adult males. The histologic changes in the lesions very closely resemble those of tuberculosis. Differential diagnosis depends on finding the specific micro-organisms. *Coccidioides immitis* (Rixford and Gilchrist, 1896) is a well-characterized species of mold belonging to the Ascomycetes. In the animal body it exists as spheres enclosed in doubly contoured capsules and multiplies by endogenous spore formation. In aerobic cultures a septate mycelium is produced and in old cultures chlamdospores, which resemble somewhat the parasitic form of the organism. In anaerobic cultures in ascitic fluid of gelatinized horse-serum to which sterile tissue has been added, the parasitic forms continue to multiply for a time by endogenous spore formation, much as they do within the animal body.

Coccidioides immitis is distinctly different from the budding fungi found in human diseases variously called blastomycosis, oidiomycosis, Saccharomycosis or blastomycetic dermatitis, of which the budding parasite, *Cryptococcus dermatidis* (Gilchrist and Stokes, 1898), is perhaps the best known.

39. **Effect of Quinin on Rabbits.**—Neither quinin bisulphate nor quinin and urea hydrochlorid—dissolved in water and administered subcutaneously—had any curative effect on rabbits which showed symptoms of rabies after intracerebral subdural and intramuscular inoculation with street virus. Subcutaneous injections of quinin bisulphate and quinin and urea hydrochlorid caused a local reaction with necrosis and, in the control rabbits, subsequent sloughing.

41. **Anaphylaxis.**—When a guinea-pig is sensitized by the intraperitoneal injection of a large amount of the serum of a rabbit immunized against horse-serum, Weil states it becomes possible by Dale's method to determine the persistence of sensitization to horse-serum over a period of fifteen days. The degree of sensitization gradually diminishes. At the same time there is a gradual development of sensitization toward rabbit-serum. Coincidentally, the presence of circulating antibodies toward rabbit-serum is demonstrated in the serum by using it passively to sensitize normal guinea-pigs. These data are interpreted to indicate that both antigen (rabbit's serum), and antibody thereto, coexist for some time in the cells of a guinea-pig immunized by large doses of a foreign serum; and that the blood at the same time contains free antibodies. The suggestion is made that the persistence of antigen in the cell is a factor which contributes materially to the resistance of animals sensitized by massive doses of antigen.

45. **Influence of Splenectomy.**—Provided the spleen has been removed for a period of time less than a week and more than two days, the intravenous injection of a specific hemolytic immune serum, in doses large enough to produce hemoglobinuria, is followed by marked phagocytosis of erythrocytes by the endothelial cells of the lymph-nodes and liver. In the lymph-nodes the process starts about three hours after the injection of immune serum, reaches its height about twenty-four hours after the infection and is practically complete in forty-eight hours, when the endothelial cells are found to contain large quantities of pigment, presumably as the results of blood-destruction.

A study of hemopsonins of the blood-serum under the experimental conditions indicated in the text fails to show that the phagocytosis of erythrocytes, so prominent in the lymph-nodes of the splenectomized animal following a fairly large intravenous dose of specific hemolytic immune serum, is dependent on local or general variations in hemopsonin in the splenectomized animal as influenced by organ extracts of normal and of splenectomized animals.

46. **Experiments in Anaphylaxis.**—The cold alcohol soluble and hot alcohol soluble—cold alcohol insoluble constituents of three lots of virulent tubercle bacilli were prepared and tested by White for antigenic properties by the anaphylactic reaction. All the preparations when injected intraperitoneally into guinea-pigs in doses of from 0.025 gm. to 0.100 gm. failed to sensitize the animals to a subsequent, intravenous injection of from 0.75 to 2 cubic centimeters of an extract emulsion of the same strain of tubercle bacilli. (The minimum fatal dose of the extract emulsion was 0.3 cubic centimeter for an animal previously injected intraperitoneally with 0.5 cubic centimeter of a watery extract of tubercle bacilli.) None of the preparations when injected intravenously into guinea-pigs previously sensitized with tuberculo-protein produced any anaphylactic symptoms whatever. The intravenous injection of the lipid preparations in animals sensitized with tuberculo-protein produced no true anti-anaphylaxis to a subsequent intravenous injection of extract emulsion of tubercle bacilli. When the extract emulsion was injected one hour after the intravenous lipid injection a slight tolerance or refractoriness was noted, but no protection was observed when the second injection was delayed for nineteen to twenty days. None of the preparations sensitized animals to a subsequent injection of the corresponding lipid.

47. **Staining of Yeasts by Gram's Method.**—It is shown by Henrici that yeast cells retain Gram's stain more firmly than the common Gram-positive bacteria, and unlike the bacteria, the cytoplasm of the yeast cell is not homogeneous with regard to its ability to retain the stain, certain granules appearing in the decolorizing cell which hold the dye longer than others. It is suggested that the ability of these granules to resist decolorization is in direct proportion to their ability to resist autolysis.

51. **Reaction of Guinea-Pig to Typhus Virus.**—There apparently exists a natural immunity in the guinea-pig, similar to that found in the monkey, to typhus fever. In Anderson's experience of 4.7 per cent. of the guinea-pigs failed on first injection to react to an inoculation of proven virulent guinea-pig typhus-fever blood. Fifty-six per cent. of the guinea-pigs tested failed to react to a first injection of blood from human cases of typhus fever.

The passage of the virus of typhus fever through sixty-nine generations in the guinea-pig apparently produced no change in its virulence or infectivity for that animal. After sixty-nine passages through the guinea-pig the typhus-fever virus showed no apparent change in its infectivity for the monkey.

52. **Attempt to Immunize Guinea-Pig against Tuberculosis.**—The authors' experiments show that repeated doses of even virulent tubercle bacilli prolong the life of the animal far beyond that of the controls. They suggest that the explanation lies in the fact that the superinjection may be held for a time in abeyance by the presence of a slight active tuberculosis focus. It is probable from the autopsy findings that all the treated guinea-pigs would have eventually died from chronic tuberculosis.

54. **Hemolysin Production by Streptococci.**—Lyll maintains that the hemolytic titer does not afford any absolute criterion of virulence. The production of a potent hemolysin in both cultures is dependent on the nature and proportions of enriching substances, the reaction of the medium and the time of incubation. The hemolysin appears to be closely associated with the bacterial bodies and not to be in solution. The hemolysin does not appear to be in the nature of an enzyme. The hemolysin is destroyed by a temperature

of 56 C. for thirty minutes. It disappears within forty-eight hours at incubator temperature. Normal serums of sheep, guinea-pig, rabbit, cow and man contain appreciable amounts of antistreptolysin. Salvansanized serums possess a markedly increased inhibitory power on the hemolytic action of streptococci. Hemolysin production is inhibited by the addition of sugar. This occurs most uniformly in the case of dextrose. It does not appear to be definitely associated with the amount of acid produced.

73. **Medical Aspect of Athletics.**—It has been proved beyond question that immoderate college athletics lead to physiologic hypertrophy of the heart. Athletic training leads at first to physiologic hypertrophy, but when prolonged and marked by severer athletic contests, Coughlin says it usually leads to hypertrophy plus dilation of a variable degree, frequently marked by valvular insufficiency. Functionally the hypertrophied heart, even when dilated and giving distinct evidence of valvular insufficiency, may prove more fitted to carry the man through a severe athletic contest than a normal heart would be. On the other hand, acute cardiac dilation occurs more frequently in athletes and men used to severe muscular strain than in the normal man and the effects are more prolonged and severe. Carefully collected statistics show that deaths of athletes are caused by the following diseases in the order of their frequency: cardiac diseases, tuberculosis, typhoid fever, pneumonia and Bright's disease. The dangerous games indulged in with fatalities in the order of the greatest danger are said to be football, baseball and boxing.

75. **Rhiniologic Aspect of Some Mental Disturbances.**—A frequently unrecognized cause of mental depression, and sometimes suicide, in Hagemann's opinion, is empyema of the ethmoidal cells. The absence of a nasal outpouring may mislead one into making a negative diagnosis, although the patient is constantly or intermittently swallowing pus-bearing discharges which perhaps unnoticed trickle down the posterior pharyngeal wall. The consequent autointoxication from the biochemical products liberated in the intestinal tract establishes a neurasthenic condition characterized by great despondency. Whether a direct action on the cerebral

association-centers may be exerted by an ethmoidal sinusitis, Hagemann says, is problematic. The lymph currents all tend in the opposite direction. Yet one might picture to oneself the possibility of noxious fluids finding their way into the brain via the sheaths of afferent nerves.

85. Conservatism in Operative Treatment of Simple Fractures.—For guiding rules in the conservative operative treatment of fractures, Woolsey says: In recent simple fractures, do not operate unnecessarily, only after nonoperative treatment has been tried and failed, as no operative treatment is exempt from danger. Be most careful as to asepsis. Use the simplest thing that meets the indications and avoid large foreign bodies in the tissues when possible. Judge each case by itself. In properly selected cases the operative treatment of fractures greatly improves the results.

92. Abnormal Arrangement of Branches of Aortic Arch.—In the subject reported by Brodnax the aortic arch was placed somewhat more to the left and on a higher level in the thorax than normal, reaching not quite to the supra-sternal notch. All of its branches arose by separate stems to the left of the median line, and in the following order; right common carotid, left common carotid, left subclavian, right subclavian. The right common carotid crossed obliquely in front of the trachea to gain the right side of the neck, in which it assumed its normal course; the left common carotid and subclavian occupied about their usual place; the right subclavian was the last branch of the arch, and was given off as low down as the body of the fourth thoracic vertebra, it then passed upward and to the right, behind the trachea and esophagus to gain its normal position in the interval between the scaleni muscles. The right vertebral was a product of the right common carotid. The branches of the thyroid axes, on both sides, arose by separate stems from their respective subclavian artery.

8. Tuberculin in Treatment of Tuberculosis.—As many cases as possible of pulmonary tuberculosis (the criterion for which was the presence of tubercle bacilli in the sputum) were collected by Stockdale and Hodson and paired off in such a way that a febrile patient was paired with another febrile, while an afebrile was paired with an afebrile. Then by lot it was decided which should be given tuberculin, so that there should be no suggestion as to picking cases. Further, as fresh patients were admitted into the hospital, it was decided by lot which should be given tuberculin and which should act as controls.

The tuberculin selected to be used was the new tuberculin residue (T. R.), and it was decided to give minute doses, increasing the doses gradually every second or third day at first and later at longer intervals in the case of the afebrile patients, while the febrile patients received a dose every fifth or seventh day. The initial dose in the former case was 1/100,000 milligram, and was increased to 2, 3, 5, 8 and 12/100,000 milligram, and then again about three-quarters as much again every dose. In the febrile cases the original dose was 1/200,000 milligram tuberculin residue. The object was to work up to the strength of tuberculin residue the patient would take without producing a reaction. When a reaction did occur the patient was kept quiet, and after a few days the same dose was repeated and if no reaction followed the treatment was continued as before. If, however, a reaction occurred a second time, then a further period of rest from tuberculin was given and was followed by a smaller dose than those which produced reaction. The maximum dose reached was 1/10 milligram, and this in the case of one patient only.

With regard to the local lesion, tuberculin seems to have done good in the afebrile cases, and such cases formed less than 30 per cent. of the total. Tuberculin was apparently harmful to the intermittently febrile patients, who formed the bulk of the series. Tuberculin had no apparent influence in increasing the weight or in improving the general condition, and in both these cases the balance of improvement is on the side of the controls.

18. **Standardization of Vaccines.**—The weight of bacteria in the dry condition according to Brown is the most satisfactory measure of quantity which we possess. The weight of bacteria in the moist state is much more influenced by extraneous, not always easily controlled, conditions, such as humidity, than is the weight of bacteria dry. Comparison of weights moist is not, therefore, to be recommended as a method of standardization. If a preliminary determination of the relation of weights moist and dry be made, then the weight moist may be taken for the subsequent manipulations required for the preparation of standard suspensions of bacteria such as are used in bacteriologic technic (agglutination, opsonic index, etc.), and for preparation of vaccines. If weight of bacteria is the most satisfactory standard of quantity available it is essential that vaccines should have their dosage expressed in terms of weight. Methods of standardization by enumeration are best carried out with suspensions of moist, young, actively growing bacteria (1) because the enumeration by colony count demands that all the bacteria used should be living, (2) because suspensions in the ordinary media used are most easily made in this way. Brown's experiments indicated that there was no loss of antigenic power during desiccation. As a method of enumeration Braxton Hick's procedure with standardized suspensions of organisms was found to be satisfactory.

Brown's method, in which an acid-fast organism was used, dispensed with the need for two standard suspensions and gave better staining results. It is necessary to ensure the adhesions (as e. g., by use of an albumin solution) of the bacteria in such standard suspensions to the slide surface, otherwise the values obtained will vary very considerably. Determination of quantity by an opacity method is easily carried out by contrasting the test suspension with specially prepared standard suspensions in tubes of equal caliber. A special instrument such as a colorimeter makes the determination still easier.

19. **Preparation of Typhoid Vaccines.**—Blaker found that the growth obtained in broth sterilized in a Koch's sterilizer is more vigorous than that in broth sterilized in an autoclave. After forty-eight hours of incubation there is evidence of commencing death of bacilli, as is evident from the plate culture method of enumeration and microscopic examination. Blaker says that the plate culture method of standardization should not be applied to a broth vaccine grown for longer than forty-eight hours as it would show too low a bacillary content. Although by means of Wright's method of enumeration standardization can be effected, even after forty-eight hours' incubation, the increasing autolysis which takes place after this period renders it doubtful whether growth should be allowed to go on longer. If allowed to do so, the accuracy of the standardization is liable to be affected.

20. **Reaction of Typhoid Inoculation.**—Of 143 patients inoculated more than nine months previously only 21 gave agglutination reactions in a dilution above one in 16, and of these 20 agglutinated in no higher dilution than one in 20. In a patient, previously inoculated against typhoid at an interval of not less than six months, a positive typhoid agglutination reaction in higher dilution than one in 40 indicates the probability of the disease from which the patient suffers being typhoid.

35. **Tubercle Bacilli in Normal Saline.**—Certain experiments are cited by Dudgeon which show the effect of storage on the pathogenicity of the tubercle bacillus. There was a gradual reduction of the pathogenicity of the bacillus stored in normal saline. No attempts were made, however, to sub-cultivate the stored bacillus direct from the saline bacillary mixture.

39. Published in the *British Medical Journal*, July 18, and abstracted in *THE JOURNAL*, August 15, p. 609.

41. **Treatment of Streptococcal Arthritis.**—O'Connor makes it a rule to operate on patients who do not promptly yield to medical treatment (sodium salicylate 3ss., sodium bicarbonate 3j., three-hourly; salines, milk diet, woolen clothing, etc.). All infected joints are opened, flaky turbid lymph is evacuated, free irrigation with warm oxygen water, drainage tubes inserted and retained *in situ* for three days. Multiple incisions are made into areas of periarticular cellulitis and not mercurial fomentations applied. Splints are employed for immobilization purposes for from seven to ten days, at the end of which the patient is requested to commence graduated active moment. When wounds are healed gentle massage is prescribed.

43. **Geographic Distribution of Appendicitis.**—Murray claims that diet is a very important factor, probably the important factor, in the etiology of appendicitis. As this disease prevails among meat-eating nations it is further probable that the view of the late Dr. Williams is the correct one, namely, that the most important constituents in our food predisposing to appendicitis are the saturated fats, such as are contained in beef and mutton. Apart from the question of diet, other contributory causes have to be considered. Irregular meals, the "quick lunch," and imperfect teeth all play their part, and the general want of physical exercise is very noticeable.

44. **Aggressins in Appendicitis and Peritonitis.**—A considerable number of peritoneal exudates were tested by Gardner for aggressive action (inhibition of phagocytosis *in vitro*). Inasmuch as aggressiveness is the direct consequence of a profuse multiplication of bacteria, the greater the number of bacteria, the more likely is the fluid to act aggressively. Early exudates therefore (first twenty-four hours) are never aggressive. Gardner found that aggressive substances are nearly always present in pus from appendicular abscesses, and they do no harm so long as the abscess wall remains intact. But they may play an important and dangerous part when a channel of communication is formed between the abscess cavity and the general peritoneum. In spreading or already diffuse peritonitis, the formation of aggressive bodies signifying as it does bacterial activity, marks the onset of a graver stage of infection. A consideration of aggressins, their origin and their action, suggests that a discriminating use of bactericidal chemicals may be of great value in the surgical treatment of peritonitis. Ether and colloidal silver are two such bodies which have undergone a successful trial.

Any exudate found in the peritoneal cavity in gangrenous or perforative appendicular peritonitis may be aggressive, unless it is very recent (twenty-four to thirty-six hours), when it is very unlikely to show any aggression, or it is quite clear and transparent, in which case it is never found to be aggressive. Thick, offensive pus is nearly always aggressive, and usually to a high degree. Appendicular abscesses in the vast majority of cases contain markedly aggressive pus. The presence of a strongly aggressive exudate in the general peritoneal cavity is a great danger to the patient. In the treatment of several varieties of peritonitis, Gardner states, closer attention might with advantage be paid to the question of bacterial multiplication, and to the direct means which are open to the surgeon of checking it. Local chemotherapy by means of drugs which kill or paralyze bacteria without damaging to any considerable degree the living body-cells, Gardner says, is not only possible, but has been proved in practice to be at least worthy of a more extensive trial.

45. **Leukemias.**—Of 59 consecutive cases of leukemia studied by Tidy and Pantou, 16 were classed as acute myeloid, 29 as chronic myeloid, 8 as acute lymphoid leukemia, and 6 as chronic lymphoid. It was evident that the clinical picture of leukemia varies with the acuteness or chronicity of the disease, and not with the lymphoid or myeloid origin of the cells. Acute lymphoid and acute myeloid leukemia are clinically indistinguishable, and so may be chronic lymphoid and chronic myeloid leukemia. Acute lymphoid leukemia has little resemblance to chronic lymphoid, nor acute myeloid to chronic myeloid, except in so far as chronic myeloid may terminate by a condition similar to the acute disease. One can distinguish by a blood examination between the acute and chronic types of myeloid leukemia, but not between acute and chronic lymphoid leukemia. The latter diseases are readily distinguished on clinical grounds. Acute myeloid and acute lymphoid leukemia can be distinguished by the type of cell present, but the conditions have been frequently confused and the clinical course is the same. The confusion has been due to a failure to distinguish between myeloblasts and lymphocytes. The differentiation is rarely if ever difficult for those accustomed to the use of Leishman's or other similar stains. In this connection the authors have found oxydase reaction to be quite useless. In no case in the authors' experience has the myeloid type of cell been replaced by the lymphoid type, or vice versa.

The effect of treatment in the acute cases has been negligible. In the chronic lymphoid cases changes have been extremely slight. In the chronic myeloid cases, some have changed little, others have changed to a remarkable degree. Those cases which have fluctuated to the greatest extent have been the youngest subjects. The blood of patients over the middle age reacts but little. There has been no instance of purpura in either of the chronic leukemias. In those cases of acute leukemia associated with purpura the spleen was invariably enlarged. Infiltrations of the skin, painful bones, and priapism occurred in no case. Oral sepsis did not appear to have any bearing on any type of the disease. The cases of acute myeloid leukemia include an interesting group of four patients whose predominant blood-cell was a so-called Rieder cell. This cell Tidy and Pantou believe to be a large hyaline, partly on morphologic grounds, since the cell may be indistinguishable from the large hyaline of normal blood, and intermediate types between the normal cell and the primitive marrow-cell were numerous; partly on functional grounds, because these cells were actively phagocytic, as are those of the normal blood. They consider that a scrutiny of these cases affords strong evidence of the marrow origin of the large hyaline cell.

46. **Fragility of Red Blood-Corpuscles.**—A method is described by Bigland of accurately and easily determining the fragility of red blood-corpuscles toward the hemolyzing agent saponin. Human red blood-corpuscles show a constant figure of resistance toward saponin hemolysis. The serum is markedly protective against the action of saponin, but this power varies within certain limits. The corpuscles of various animals show marked variation in their fragility. In jaundice the resistance of the washed red blood-corpuscles is markedly diminished, while the protective action of the serum is markedly increased. This latter result is not due only to the antagonistic action of saponin and bile salts. In all the anemias, except pernicious anemia, the corpuscular resistance is increased. In pernicious anemia it is normal or slightly diminished. In splenic anemia there is great increase in corpuscular resistance, and the serum appears to have no protective reaction. In the anemia found in malignant disease, syphilis, tuberculosis, scurvy, amyloid disease and myelogenous leukemia, and in a case of splenectomy, there was an increased corpuscular resistance. In diabetes the corpuscular fragility is normal, while the serum in some cases is abnormally protective. In exophthalmic goiter and paroxysmal hemoglobinuria the corpuscular fragility is normal. In polycythemia the resistance is increased. A high temperature appears to increase corpuscular fragility.

55. **Meningeal Symptoms in Scarlet Fever.**—Mauriac and Philip report the case of a child with unsuspected scarlet fever who suddenly developed epileptiform convulsions from severe uremia affecting the central nervous system. Under treatment the condition improved, the child roused and the temperature returned to normal, but the third day it ran up again and the child died in coma. Pneumococci were cultivated from the cerebrospinal fluid and there was a high urica content as also in the blood. In a second case the mild scarlet fever without albuminuria had been properly treated

but during convalescence the girl of 15 got chilled one evening and fulminating subacute nephritis with pulmonary edema followed and soon proved fatal. The extreme gravity of abortive, unrecognized forms of scarlet fever and the complexity of scarlatinal and uremic meningeal conditions are emphasized by these cases and some others cited. There were none of the signs of actual meningitis, no Kernig, no stiff neck, no vomiting; the convulsions dominated the clinical picture. The meninges evidently suffer in scarlet fever and one must be on the lookout for superposed acute infection. The prognosis otherwise depends on the degree of the retention of urea. A high temperature accompanying the convulsions suggests superposed infection.

58. **Hemorrhagic Pleurisy.**—Creyx says that when the effusion is hemorrhagic, clots may form and impede the escape of fluid when the puncture is made at the lowest point, which otherwise is the preferable technic.

63 *Snapping Joints. (Les articulations à ressort; Subluxations volontaires intermittentes des articulations.) P. Bertein. Commenced in No. 5.

61. **Treatment of Deformed Fingers.**—Morestin refers to fingers permanently contracted as the result of some pathologic process in them or in the vicinity. Treatment is as simple as it is effectual when all the obstacles preventing the use of the finger are cut away in turn, the scar tissue, the debris of tendon sheaths, the muscles and the shriveled ligaments, passing systematically with minute care from one to the other until all that interferes with the straightening of the finger is done away with. The triangular or square flaps cut to alternate and turn back for access to the deeper soft parts, can be brought back to cover the defect, utilizing also the cicatricial tissue that has been binding down the finger, and the result is quite satisfactory, much more than would be anticipated. He has found it possible in this way to restore practically complete function to a thumb, for instance, left absolutely crippled after an abscess or other lesion. He makes no attempt to restore the tendons. The fingers can serve very useful purposes without the tendons; the muscles of the thumb suffice to bend it, and a finger once rendered flexible bends with the others. All his patients had the wage-earning power of the hand restored. He gives an illustrated description of five peculiarly striking cases.

62. **Calculus in the Pancreas.**—Lacouture and Charbonnel report a case in which a calculus was successfully removed from the pancreas, which was opened back of the duodenum. They have found only 133 cases of pancreatic lithiasis on record, including 16 in which operative treatment was applied. In their case roentgenoscopy later showed that the woman of 32 still has five very small calculi left in the pancreas. Although she feels well except for slight pain under the right costal arch, yet she is kept on a diet free from meat and fat in order to spare the pancreas as much as possible. In 5 of the 16 operative cases the stone could not be found and 3 of the patients died, as also 2 others requiring extremely complicated operations. The mortality was thus 34 per cent.; and 1 patient died several years later from pancreatic diabetes. The final outcome otherwise is not known except in 3 cases in which the patients were in good health after from four to fourteen months.

63. **Snapping Joints.**—No cutting is required as a rule to correct this tendency to volitional, intermittent subluxation in a joint. A plaster cast will hold the parts in place and

give the stretched capsule a chance to retract and put an end to the abnormal play of the parts. Afterward the joint should be kept from overuse.

68. **Transplanted Connective Tissue.**—Rehn and Miyauchi give an account of their experimental research with skin and subcutaneous connective tissue used to substitute tendons, ligaments, etc., and fourteen clinical cases in which the method was successfully applied. Whether used as a twisted cord or flat sheet, it healed always in place without signs of irritation and answered its purpose perfectly either as a tendon, a ring to reenforce a sphincter, or a broad strengthening band. It seemed to answer the purpose fully as well as fascia or tendon flaps.

69. **Cystic Goiters.**—Riedel states that among the 1,075 patients who were operated on for goiter in his service, large cysts were found in the thyroid in 148. He here discusses the disturbances and dangers to which a tendency to such cysts exposes the patient.

70. **Tying off the Pylorus.**—Guleke has recently reexamined nearly all of the thirteen patients who required exclusion of the pylorus; this had been done by ligating it with silk. Two died in a few weeks from preexisting complications. The others were found all in good condition, the pylorus still completely shut off. He does not regard this method of ligating the pylorus as superior to others but his experience indicates that it is feasible and gives good results when special circumstances render it necessary to hasten the operation and bring the patient out from under the anesthetic. The eleven cases are reported in detail.

71. **Resection of the Stomach for Ulcer.**—Perthes reports that among 40 operations of the kind, the 18 patients treated by transverse resection all made a smooth recovery, while 2 died of the 17 with resection of the pylorus for a hard ulcer and one after resection of the middle half of the stomach. He has learned that 2 of the 11 patients with hard ulcer have died since from cancer, and this is probable also in a third fatal case. Even the resection did not save these patients.

All the other patients are in excellent condition and have gained materially in weight. Some complain of an insatiable appetite; they are ready to eat at all hours of the day, but not much at a time. Roentgenoscopy has explained this as due to the abnormally rapid emptying of the stomach after

food is taken; the stomach being more of a straight tube, the food passes rapidly along and the lack of gastric digestion has to be made up by more frequent meals. The pylorus gapes all the time in these cases. These findings were obtained only in certain cases; in others the appetite seemed to be normal and roentgenoscopy showed that the food remained the usual time in the stomach. The secretion of gastric juice, however, was materially reduced in both classes of patients. The excellent general condition shows that the bowels are able to compensate for the deficiency in gastric digestion.

72. Postoperative Ventral Hernia.—Sprengel's article was the address to open the discussion on this subject at the last German Surgical Congress. It is illustrated and closes with the warning that the danger of postoperative hernia depends on the mode of the incision and its location; the upper abdomen is less liable to it than the lower. The principle of alternating and transverse incisions is unmistakably superior to the single incision. There is still uncertainty as to the best technic further, but there seem to be no reasons for prophylactic plastic operations to ward off ventral hernia. He does not approve of using an autotransplant of muscle tissue to correct a postoperative abdominal hernia, preferring an unpedunculated fascia flap for the purpose. Paralysis of the abdominal walls and extensive stretching of the side walls of the abdomen must be regarded at present as beyond hope of a cure.

74. Total Peripheral Anesthesia from Intravenous Injection of Local Anesthetic.—Meyer made an intravenous injection of cocaine in dogs and cats and gives the details of twelve such experiments. The injection was preceded by a little morphin and scopolamin, and the results confirmed those published by Meltzer, Kast and Ritter in regard to the total peripheral analgesia thus induced. Even the peritoneum seemed to be totally free from sensibility. Contact was evidently felt but no pain. The analgesia seemed to be restricted to the periphery; the peripheral nerve terminals to which the anesthetic is brought by the blood feel the effects while the nerve trunks escape.

78. Postoperative Necrosis of the Pancreas.—Jenckel states that he has had 11 cases of acute or subacute necrosis of the pancreas in his service in the last three years, and in two instances the necrosis had followed on an operation. In one of these latter cases the operation had been the removal of a cancer in the sigmoid flexure in a man of 56; in the other case a large ovarian cyst had been removed from a woman of 64. There had been nothing previously to suggest any pancreas trouble, and the acute necrosis developed soon after the operation and proved fatal the sixth and sixteenth days. He is inclined to ascribe the necrotic process to the resection of the omentum which had been required in each of the cases. Retrograde embolism followed, and this injured the pancreas tissue and started the autolysis.

81 *Reflex Epilepsy and Its Operative Treatment. S. Kalischer.

79. Thorax Surgery and Differential Pressure.—Steinmann lists 221 articles bearing on this subject and compares the experiences and views of the various writers with his own clinical work. He expatiates on the great value and importance of the differential-pressure procedures not only as an almost indispensable aid in operations on the thorax, but as also of service in revealing a wound in the lung by the air streaming through it, in locating foreign bodies, and in facilitating ligation or gentle clamping to expel the blood from a lobe. Another great advantage is that the suction of air aspirates out blood, mucus and pus in opening an abscess or other cavity in the lung. This is found extremely useful often in changing the dressings. Küttner made an

opening into a bronchus in a case of deep stenosis of the trachea, thus permitting retrograde respiration. Differential pressure is also of great service in operating on the heart; in fully 80 per cent. of all wounds of the heart the pleura is injured likewise. Exploratory thoracotomy under differential pressure is now a routine measure, and by alternating positive and negative differential pressure, artificial respiration can easily be kept up indefinitely.

80. Iodine and Exophthalmic Goiter.—Kempner concludes from the literature on this subject that there can be no doubt that iodine, even in minute doses, is liable to elicit Basedow symptoms in persons with a goiter. The evidence further shows that true Basedow may develop from an acute thyroiditis. Three authors have published cases in which patients with clinically normal thyroids developed Basedow symptoms while taking iodine for arteriosclerosis, tabes or a false tumor in the brain. Romheld and Pineles have noticed a connection between an iodine-Basedow and an inherited taint such as diabetes, obesity, Basedow or neuropathy. This confirms anew the close connection between the iodine-Basedow and other glands with an internal secretion as well as the thyroid; possibly the Abderhalden reaction might throw light in these cases. Ohlemann does not agree with other writers on this subject; he states that exophthalmic goiter was favorably influenced in his own person by 10 or 20 drops daily of a $\frac{1}{3}$ solution of potassium iodide, kept up for six weeks; his pulse-rate dropped by 68 beats. Later, he took 2 to 4 drops of tincture of iodine (P. G.), his pulse going down to 72 in ten days and the improvement persisting for ten months after this treatment. He thinks that too large doses are responsible for the unfavorable effects experienced by others.

Kempner warns that a family predisposition to goiter, Basedow and aneurysm of the aorta is sometimes evident, and calls for special caution in giving iodine. Kienböck found the thyroid slightly enlarged in nearly every case of dilatation or aneurysm of the aorta in men, and noted signs of hyperfunctioning on the part of the thyroid in most of the cases. He explains the tendency to goiter in these cases as the result of venous congestion from the pressure of the enlarged aorta. It is possible however that the thyroid may have become enlarged under the influence of preceding iodine treatment, or that both the thyroid symptoms and the aorta affection can be referred to a common cause, some upset in the ductless-gland system.

81. Reflex Epilepsy.—Kalischer applies this term to cases in which the epileptic seizure is a reflex reaction to peripheral irritation. His analysis of eighty-four articles published on the subject shows that in a large number of cases hysteria alone can be incriminated; in others the trauma was merely a contributing factor with a predisposition. At the same time there are cases on record in which lesions of the skin, mucosa, bones and meninges were evidently responsible for the epilepsy, and the latter was cured by appropriate treatment of the peripheral lesion. An interval of five years at least must be required before speaking of an absolute cure.

83 Mechanical Treatment of Tuberculous Lung. (Zur intra- u. extrapleurale Collapstherapie bei Lungenphthise.) W. Knoll.

82. Pernicious Anemia in Children.—Kusunoki reports from Basel the case of a girl of 6 with anemia of unknown cause. The color-index was high, the reds dropped from 1,868,000 to 510,000 and the hemoglobin from 40 to 10 per cent. in the course of five weeks. The presence of megaloblasts and megalocytes, absence of leukocytosis, the tendency to hemorrhages and all the histologic findings testified to true pernicious anemia. Several lymph-nodes were swollen but this is of such common occurrence in children that it can be disregarded in the diagnosis. Streptococci were cultivated from the tonsils. He reviews the few cases on record of pernicious anemia in young children, remarking that some of them evidently belong in other categories.

91. The Leukocyte Count in Miliary Tuberculosis.—Wack declares that in miliary tuberculosis there is a relative decrease in the lymphocytes. This is found in cases in which there is no secondary affection, showing it to be due to the tubercle bacilli alone. There is a temporary decrease in the total leukocyte count in many cases. This is of value in the differential diagnosis from typhoid, purulent meningitis and pulmonary tuberculosis. A case is described that showed the clinical and hematologic picture of acute myeloid leukemia. Autopsy revealed subacute miliary tuberculosis. Roth believes that the miliary tuberculosis was the cause of the myeloid leukemia. Several similar cases have been described in the literature. The severity of the infection causes an early interference with the function of the bone-marrow, so that immature forms of cells are discharged into the blood.

96. Treatment of Recently Acquired Gonorrhea.—Merk gives the patient a set of vials each containing a mixture of 0.03 gm. silver nitrate and 0.025 gm. potassium permanganate in pulverized form. When ready to use this is stirred into 0.25 liter of freshly boiled tap water. No syringe is used, merely a catheter No. 9, French, with two openings at the tip and flaring outer end. The fluid still as hot as it can be borne by the urethral mucosa is drawn up into a rubber bulb and then forced out into the funnel opening of the catheter. It thus rinses out the urethra from the rear, and large amounts of fluid can be used. If the tap water contains salts that precipitate the silver nitrate, he varies the amount in the vials to correspond. The procedure is repeated three or four times a day and the whole technic is so extremely simple and easy that the patients apply it systematically and seldom shirk. Merk describes the biologic and chemical factors involved in the action of silver nitrate and shows how none of the would-be substitutes shares its truly potent properties, and how the claims made for some of the proprietary substitutes exalt into alleged advantages what are really drawbacks.

104. Anticholera Inoculations.—Savas states that there was no cholera in Greece or its dependencies until Grecian troops invaded Bulgaria last July and entered cholera-infested cities after fighting their way over 250 to 300 kilometers in twenty-six days. Refugees to the number of 150,000 also poured into Greece from various directions, and thus cholera broke out almost at once in many towns. Even Saloniki had 600 cases. As soon as the truce was proclaimed, systematic inoculation of the troops and populace was commenced and the epidemic was arrested. Fully 2,503 soldiers were treated for cholera in the hospitals, with a mortality of 515 (20.6 per cent.), including 27 officers and 9 surgeons, with recovery of 22. The number of cases in old and new Greece was 5,200 and 5,300, with 1,665 and 1,700 deaths. Savas prepared 1,000 liters of cholera vaccine and had twenty flying cholera laboratories at work, and in three months had vaccinated all the troops, a total of 150,000 men, and 350,000 of the populace, a total of 500,000 souls. When possible each person was inoculated twice with an eight-day interval. The vaccination was done by the regiment's surgeons, and never to but a small part of the regiment at one time. It never seemed to interfere with their military duties.

Savas gives tables which show graphically the success of the measure. For instance, in the whole army 19 per thousand developed cholera: 93 per thousand among the unvaccinated; 42 per thousand among those inoculated only once, and 7 per thousand among those who had been twice inoculated. The mortality among the unvaccinated was 27.5 per cent. while it was 12.2 among those inoculated once and 10.2 per cent. among the twice inoculated. Cholera soon disappeared from the infested towns after the dual vaccinations.

105. Changes in Spinal Fluid after Injection of Neosalvarsan.—Biach and his coworkers state that in nine of twelve cases sugar appeared in the spinal fluid after injection of salvarsan or neosalvarsan. The findings are tabulated and compared with an equal number not given salvarsan treatment. The stage of the syphilis or the reaction otherwise to the injections did not seem to influence the sugar content. It seems evident that individual conditions are responsible for the appearance of the sugar. Persons with it are, possibly, more liable to react to salvarsan with nervous symptoms.

108. Nephritis and Child-Bearing.—Cecikas thinks it is more than a casual coincidence that only eight of his twenty-eight married patients with nephritis have borne healthy children; abortion was common and five of the women never conceived.

- 112 Woody Phlegmon and Inflammation of the Thyroid. (Flemmone ligneo del Reclus e tiroidite lignea del Riedel.) U. Cavalli.
113 Operative Cure of Gastric Cancer. G. De Francisco.

112. Woody Phlegmon.—Cavalli reviews the present status of our knowledge in regard to woody phlegmon and woody thyroiditis. Everything tends to show that they are identical processes and that nothing more is required for either than simple incision and draining at most. In a case reported, the large woody phlegmon developed in the abdomen after an operation for hernia which had been followed by an abscess and expulsion of the silk sutures. The patient was kept in bed, ichthyol packs applied with moist heat, and potassium iodid was taken internally. The hard swollen

4. *Massage*.—This may be a helpful measure when the manipulation of the abdomen is done by some one with general anatomic knowledge and special information about the abdominal organs of the patient under treatment. It should not be instituted if there is any suspicion of a duodenal ulcer, a chronic appendicitis or other inflammatory condition. The bladder should always be empty. The massage may be either superficial or deep. It may be performed by kneading, by a rotary motion in which the abdominal wall slips over its contents, by a rapid vibratory motion, or by rapid slapping with the edge or flat side of the hands, always with a general movement in the direction of the colon. It may be given with a mechanical vibrator. Self-massage may be carried on by rolling a cannon ball, or ball of clay covered with chamois skin or leather, or a wooden ball filled with shot, over the abdomen in the direction of the colon.

5. *Support of the Abdominopelvic Walls*.—In defecation, normally the anterior abdominal muscles, the diaphragm and the pelvic floor contract or are set so as to raise intra-abdominal pressure. In most cases with ptosis of the viscera, however, not only do the weak abdominal muscles fail to make pressure, but also, by allowing the viscera to fall away from the diaphragm, they deprive this latter of its usual resistance. It is therefore difficult to raise intra-abdominal pressure. Hence an inelastic support extending around the body and from navel to symphysis should be applied the first thing in the morning and worn till bedtime. In addition, if there is laxity of the pelvic floor, this should be attended to by a pessary or the necessary surgery.

6. *Foods*.—So far as their effect on the bowel movements is concerned, foods might be classed according to the chemical substances they contain, and the amount and character of their residue. They tend to promote peristalsis: (1) by increasing the bulk of the intestinal contents, as by their structural parts such as cellulose, skins, etc., and by unabsorbed oils and fats; (2) by mechanical irritation, as by seeds or husks; (3) by chemical action, as by sugars and fruit acids and their salts, and digestive products, such as soaps, amino-acids, etc.

It goes without saying that those who habitually undereat will be constipated; in fact, simple undereating is a frequent cause of constipation. The same is true of those who habitually eat food that is too readily digested. In either case the residue is insufficient. Therefore, abundant mixed meals usually favor bowel movements. For residue, cellulose, as furnished by fruits, vegetables, and other plant products is of very great importance; in fact, Rubener states that in the absence of cellulose almost everything is absorbed. Substances rich in cellulose pass into the intestines as paste and stimulate peristalsis, while meat, eggs and milk pass along as liquids, and so favor segmentation, but not peristalsis (Cohnheim). The products of the latter type are then rapidly absorbed and leave but little residue. Hertz reports that of the dry substance of meat, eggs, white bread and rice, only 5 per cent. appeared in the feces; while of the dry substance of green vegetables and brown bread 15 per cent., and of the dry substance of carrots and turnips, 20 per cent. was recovered. The feces of a mixed diet gave 100 gm. of water and 35 gm. of dry substance; the feces of a vegetable diet, 260 gm. of water and 75 gm. of dry substance.

Vegetables and salads mostly contain much fibrous tissue and cellulose. Many of them should be quite as much esteemed for the residue they leave for the bowels as for the nutritive matter they furnish for absorption. Such are lettuce, spinach, carrots, parsnips, oyster-plant, turnips, cabbage, cauliflower and squash. The salad dressing may be a means of furnishing abundant oil, which tends to be laxative.

Farinaceous foods include the cereals, the starchy vegetables, such as potatoes, and foods made with flour, such as bread. The cereals contain more or less cellulose. Oatmeal is especially laxative, because of the presence of indigestible husks and excessive cellulose and fat. It is often taken in the form of crackers. White bread leaves very little residue, but bread, biscuits and crackers made of graham flour, or containing bran, leave a large residue and tend to be laxative. It is to be remembered that graham flour is made by grinding the whole of the wheat kernel, bran and all, and is not bolted, so that it contains coarse particles. The so-called whole-wheat or entire-wheat flours have a portion of the bran removed and are bolted, but are coarser than white flour.¹

Fats tend to be laxative largely because of the soaps which are formed from them in the intestines. They may be given in the form of cream, butter, olive oil, etc. It goes without saying that the greater their nutritive power the less is their laxative effect; for if they are absorbed they do not pass on to the colon.

Fruits contain sugar, cathartic acids or salts, indigestible structural parts (fiber, cellulose, skins, etc.), seeds and non-absorbable colloid pectin bodies. Those most frequently considered laxative are prunes, figs and dates; but an apple, an orange or some grapes at bedtime or before breakfast will often insure the morning stool. Of this latter group, the acids and salts belong to the saline cathartic class. In young children one or two teaspoonfuls of orange-juice may be an effective stimulant to the bowel, its acid changing in the duodenum to the laxative sodium citrate.

Fruits and other coarse foods have the great disadvantage that they tend to promote gastric hyperacidity and flatulence. In obstructive or spastic types of constipation they may impede the action of the bowels, or may even form a food ball in the intestines. In one case, Coerr² removed from the ileum a ball which weighed 945 gm. and was composed of cereal husks, fruit seeds and other plant parts. In a number of instances we have found that the bowels acted better when the patient stopped fruit-eating.

7. *Water-Drinking*.—In those who live on a dry diet constipation is the rule; but the converse is not true, for the ingestion of large quantities of water does not make the bowels move. In two normal cases and six cases with chronic nephritis, we observed the effects of the administration of 8 ounces of water each hour for fifteen hours daily for one week. That was 7½ pints of water a day by mouth. In the normal cases the only noticeable effect was increased urination, the bowels not showing any increased activity. In the kidney cases the only observed effect was edema, neither the kidneys nor the bowels being appreciably increased in activity. As a matter of fact any excess of water is normally absorbed from the intestines with rapidity, and in any but kidney cases it serves to activate the kidneys rather than the bowels. Such absorp-

1. Bull. 143, U. S. Dept. Agric.

2. Coerr, F. D. H.: Enteroliths, THE JOURNAL A. M. A., Dec. 20, 1913, p. 2238.

tion of water may, however, be greatly retarded by the solution in the water of salts containing poorly absorbable ions, such as the saline cathartics, or by substances in the digestive canal that hold the water, such as agar-agar (See next paragraph). And since, in order to keep the feces of a soft consistency, the food residue must hold a certain amount of water, the drinking of a reasonable amount of fluid should be prescribed for those who habitually underdrink.

8. *Medicinal Agents Which Give Bulk and Soft Consistency to the Feces.*—The more commonly employed ones are: agar-agar, liquid paraffin, and small (not expulsive) doses of the saline cathartics.

1. Agar-agar absorbs water and increases greatly in bulk, so that it softens and enlarges the fecal mass. It is not absorbed unless changed bacterially, but it has the disadvantage that if it is not carried out, it forms a most excellent culture medium for the growth of intestinal bacteria. It is not a very effective laxative and usually requires the addition of a little phenolphthalein or cascara. Used in a similar manner are flaxseed and psyllium seeds, which absorb water, become mucilaginous, and increase the fecal bulk. They serve the purpose of making the bowels move, but they are very subject to fermentation, with the development of gas in the intestines.

2. Liquid paraffin (*petrolatum liquidum*) is a remedy that has been extensively employed since it was called to the notice of the profession by Sir Arbuthnot Lane. It is a viscous liquid that is not at all changed chemically and not at all absorbed from the alimentary tract, as shown by Bradley, 1911, and by Bloor, 1913, hence it serves to soften and to increase the bulk of the feces. It is also believed to be strictly non-irritant. Whether or not it exerts in the bowel a disinfectant effect on some of the strains of fecal bacteria has not been demonstrated. Finch and others have shown that it lacks disinfectant effect, but that, by virtue of its viscous and oily nature, it acts as an agent which retards the growth of bacteria implanted in it, but this does not serve as a test of its antibacterial value when mixed with food residue in the ileum or colon.

The refined oil is almost tasteless, is readily swallowed without any added flavor, and in doses of from 1 to 3 ounces a day is a mild but often efficient laxative. On account of its oily nature, it should not be taken just after meals, but preferably when the stomach is empty, that is, about an hour before lunch and dinner and at bedtime, for the oil will retard gastric digestion and prolong the emptying time of the stomach. In some cases, especially those in which the stomach-emptying is already retarded, the oil is not well tolerated, causes nausea or regurgitation, and has to be stopped. In others of the chronically constipated, the oil leaks from the anus so that it greases the clothes, yet without giving a proper stool; or it passes down as free oil without admixture with the food residue. In these cases reduction of the dose of oil and persistence in its use may meet with the desired result, but a small dose of another laxative, such as cascara, may be necessary.

On account of its recent extensive use as an internal remedy, a few words in regard to the quality and properties of this oil may be in order. It is quite generally asserted that the Russian oil is superior to the American for two reasons: (1) the absence of the harder paraffins, and (2) the absence of members of the olefin series of unsaturated hydrocarbons. But in the best

American oils the paraffins are removed by chilling, and according to Sir Boverton Redwood, in his extensive work on petroleum, there is no sufficient evidence that the unsaturated hydrocarbons of Pennsylvania petroleum are olefins, and that, in any case, if there are any present they are readily removable by strong sulphuric acid. Redwood further states that "comparison of results obtained with American, Galician and Russian petroleum shows that the same classes of hydrocarbons—the paraffins, the polymethylenes or naphthenes, and the aromatic hydrocarbons—are present in the petroleum from all three sources, but that the relative amount of naphthenes and in all probability of aromatic hydrocarbons is greatest in Russian and least in American petroleum." Marcusson³ claims that, of stable saturated hydrocarbons which react with fuming nitric acid, the Russian oils contain a higher percentage than the American oils. There is obviously some difference between the Russian and American oils, but in the well-refined products the difference is not marked.

As a matter of fact, after a certain fraction of petroleum of the specific gravity desired has been obtained by repeated fractional distillations, the regular process of refining is to subject it to the action of strong sulphuric acid, then caustic alkali, and then water for thorough washing. A stream of dry air carries off the water. In some instances the oil is filtered through diatomaceous earth or bone-black. This refining process must be repeated many times, indeed as often as fifteen or sixteen times, perhaps, and it correspondingly increases the expense of production.

The proposed text for the Ninth Revision of the U. S. Pharmacopeia describes "liquid paraffin" as free from fluorescence, without odor or taste, and not acted on or colored by concentrated sulphuric acid or nitric acid in the cold. The British Pharmacopeia specifies that when the oil is mixed with an equal volume of sulphuric acid in a test-tube and placed in boiling water for ten minutes with frequent agitation, the color of the separated layer of acid should not be of a deeper tint than pale brown.

I have tested a number of oils on the market. Of nine samples which have been mixed with an equal volume of sulphuric acid, a portion not having been heated, and a portion having been heated on a water-bath for ten minutes, nearly all fail to come up to the requirements. Three of these samples are American and are fluorescent. The others are sold as Russian oil. Obviously the oils on the market are of very poor quality.

We do not yet know whether, when used internally, an oil is or is not harmful if it is not fully refined; but till we do know, it is the part of wisdom to demand only the very best.

In regard to the specific gravity of these oils, it would seem that the more viscous oils, those of specific gravity from 0.880 to 0.890, are the ones of choice. I have been of the belief that lighter oils than this were likely to pass through the bowel without satisfactory admixture with the feces; but in a study of this subject, I find that there is no rule about it, and that at times in certain patients, the heavier oils as well as the lighter will give a stool of pure oil or will leak from the anus. The question of the requirement of a high specific gravity must, therefore, remain an open one.

3. Marcusson: Chem. Ztschr., 1912.

The more solid paraffin preparations, such as white petrolatum have also been employed in the form of a flavored and usually colored jelly. They are apparently just as active as the liquid preparations.

3. Of the saline cathartics, the softening doses are smaller than the usual expulsive doses; for instance, 1 or 2 drams of magnesium sulphate or milk of magnesia are given at bedtime, or morning and night. They act by retarding the absorption of water and so increasing the amount of water that reaches the colon. This prevents too great concentration of the feces in the colon. The larger expulsive doses of saline cathartics should not be used daily for any length of time, for they bring about a "peristaltic rush" for one or two hours only, and accustom the bowel to an entirely abnormal action.

Of the anthracene cathartics, senna, rhubarb, cascara, aloes, aloin and phenolphthalein, little need be said, for they have been prescribed with great benefit by the profession for many years.

At times the use for a few nights of an injection of one pint of warm olive oil to be retained through the night, together with one of the softening agents by mouth, will have a wonderful effect in starting the bowels on a new line of activity. Indeed, a number of the chronically constipated referred to us for advice as to the need of surgery, have apparently completely overcome their chronic stasis by this treatment. Sometimes it is wise to renew the oil injections for about one week in each month.

Having thus reviewed some of the simpler remedies, we might sum up the treatment of chronic intestinal stasis as follows: Regularity of defecation, measures to improve intra-abdominal pressure, measures to increase peristaltic activity, and measures to increase the bulk and softness of the colon contents. In the average case attention to habits of life and to the amount and kind of food, and the administration of a softening agent or a very mild laxative will be effective in overcoming the stasis, and, therefore, the toxemia. In severe cases, the addition of an oil enema at night may work a marvelous change for the better. In these chronic cases the drastic cathartics should be omitted from use.

If measures such as those spoken of, when carried out thoroughly, do not overcome the stasis and the toxemia, the question of surgery should be seriously considered.

57 West Fifty-Eighth Street.

ABSTRACT OF DISCUSSION

DR. T. F. RILEY, New York: This question of intestinal stasis every practitioner must face. One or two points with regard to constipation may be mentioned. Many people who drink beer at night have free movements in the morning; light beers produce this, also buttermilk. Whether it is due to the liquid or to acid fermentation is a question. Chronic constipation is sometimes due to tightened sphincter. One should always examine the rectal sphincter. Its dilatation in children and infants will often cause the child to have a regular daily movement. In adults the use of dilators is often successful in producing these results. Bran is now popular, but, in its ordinary form, it becomes wormy and filled with vermin during the summer. A number of firms are putting out sterilized bran. I believe the large quantity of sulphur contained in the American mineral oil is distasteful to the patient. Whether a patient is benefited by the use of the oil or by the cathartics of the cascara series is a question. It is more disagreeable to take the oil than the tablets and the

results do not warrant the use of the oil in preference to the tablets in many cases.

DR. GEORGE PARKER, Peoria, Ill.: Does or does not phenolphthalein produce albuminuria?

DR. ROBERT A. HATCHER, New York: How about aloin used alone? We know that belladonna or atropin in small doses stimulates the vagus in the splanchnic area and there is a secretion in the pancreas which is due to this stimulation, and if atropin has this activity then it should have just as great an action on the liver. I would say that a good specimen of aloin is just as good as aloin, belladonna and strychnin. The specimen, however, must be good.

DR. W. A. BASTEDO, New York: I never heard of any special effect of beer on the bowels. I did not include consideration of the tight sphincter, as when there is such an obvious reason for constipation as that we should find it out. In normal people there are no feces in the rectum, or only a few remnants. When there are feces in the rectum and the patient is not cognizant of the fact, then we have a troublesome condition with which to deal. There is usually atony of the walls as well as lack of sensitiveness. Replying to Dr. Hatcher, in a number of instances I have tried aloin pills and aloin, belladonna and strychnin pills on the same patient, and the simple aloin pills did not work so well. It is true there is sulphur in the American oil, but this is not the cause of the excessive darkening with sulphuric acid in these samples. Undoubtedly the American oils are less well refined than they might be, for the samples shown are the best oils available on the American market. Two of them also are fluorescent and according to the pharmacopeia should not be used. Rowntree found that when phenolphthalein was given by the mouth it was not found in the urine, but when given hypodermatically it was excreted by the kidneys. I have noted that, at times, in patients taking only laxative amounts of phenolphthalein by mouth, the urine will at times turn pink on the addition of alkali. This would indicate some absorption with excretion by the kidneys. It does not cause albuminuria.

INTERNATIONAL STANDARD FOR TESTING VISION AND STANDARDIZING OTHER VISUAL TESTS*

EDWARD JACKSON, M.D.
DENVER

The cards of test-letters in common use are admirably adapted to the subjective determination of errors of refraction; but as a test for visual acuity they probably afford the poorest and most inexact standard on which any scientific observations are now based. As a standard for visual acuity, test-letters belong to the stage of mental and scientific development when the standard for length was "three full grains of barley corn taken from the middle of the ear," or "the distance a man can walk between sunrise and sunset."

As a help in the subjective measuring of refraction they are superior to any substitute that has been proposed and are not likely to be given up. But as a scientific standard they possess two essential defects:

1. The different letters when made as uniform as possible are visible from very different distances. This makes them unsuitable for a scientific standard.

2. They can be readily committed to memory by all who are sufficiently familiar with them to make them a convenient test. This lessens their value as a practical test.

* Read before the Section on Ophthalmology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

For these reasons test-letters should be standardized before they are used as a basis for records of visual acuity, and they should not be used when testing visual acuity is the only purpose to be served.

Every one who has attempted to establish a scale of test-letters has been struck by their differences in visibility. When Snellen attempted to make letters uniform by using a block-letter in which the lines and minimum spaces should have a uniform width, subtending a 1-minute angle at the standard distance, each letter to occupy a 5-minute square, he rejected as unsuited to the purpose the letters I, J, M, Q, W and X. Green carried the process farther, rejecting twelve letters and using fourteen. Oliver used only seven, but he still admitted letters that varied as much as 40 per cent. in visibility. The logical conclusion was reached only when a single set figure was adopted as the test, as in Snellen's optotypes for the illiterate published in 1873 (Fig. 1 A).

Fig. 1.—A, Snellen's optotypes. B, Jackson's incomplete square subtending an angle. C, Landolt's broken ring.

Before this section at the Nashville meeting in May, 1890, I proposed the simple form of the incomplete square, subtending an angle of 3 minutes (Fig. 1 B); in 1889 Landolt had suggested the broken ring (Fig. 1 C), and at Naples in 1909 the International Ophthalmological Congress adopted the broken ring as an international standard test for visual acuity, the most important official action that has ever been taken by an international ophthalmological gathering. Either one of these tests furnishes an exact measure for visual acuity, so far as visual acuity is capable of exact measurement, and one enormously superior to any furnished by letters, numerals or any series of conventional figures.

The difficulty of using a series of differing figures for a scientific test has been encountered by every one who has attempted to arrange a series of test-type, but few have appreciated the impossibility of an accurate standard of visual acuity resting on such a basis. In

Fig. 2.—One of Dennett's lines of test letters. All about equally visible at 20 feet.

1885 Dennett¹ read before the American Ophthalmological Society a paper on test-type in which this unsuitability of letters to furnish a standard test was well brought out. More recently it has been illustrated by the work of Gebb and Löhlein.² Dennett took the block-letters of the forms used in Monoyer's test-card, and found that letters 25 mm. in height could be recognized at distances that varied from 10.3 meters for the B and S, to 17.7 meters for U. He analyzed the differences of visibility and proposed and arranged test-cards in which the letters of each line should all be visible at nearly the same distance. To show how different such a test is from those we are accustomed to rely on, a line from one of these cards is reproduced in Figure 2.

So far as I know Dennett's tests have never been extensively used. While they would be superior to any other published series of test-letters for the scientific testing of visual acuity, they are not quite equal to the international standard for this purpose, and are distinctly inferior for the other purpose for which test letters are employed, the subjective determination of errors of refraction.

It would be absurd to spend time arguing the unfitness of letters as ordinarily printed on our test-cards for making scientific measurements, if they were not almost universally employed for that purpose. To use a tape measure that would spontaneously contract to 20 inches or stretch to 36 inches would be an absurdity of the same order as to use as equivalents letters, some of which can be just recognized at 20 feet and others at 36 feet, calling them all 20-foot letters.

Fig. 3.—Different forms of the same letter inscribed in squares of the same size, subtending an angle of five minutes at about 30 feet.

Such is the variability of letters of a single style used on a single card. The recognized forms of letters, even of capital block-letters, to be found in a well-equipped printing establishment, run into the hundreds. Three or four fairly distinct types of block-letters are in use on our test-cards. The differences of visibility vary with all these different forms. One firm has put out test-cards on the five-minute basis and others on a four-minute basis. The letters on the latter, although only four-fifths the height, can be seen quite as far as those on the former, because they are of simpler form. The block-letter U, if made as at A in Figure 3, can be recognized 50 per cent. farther than if made as at B in Figure 3. When to these differences in the letters of the roman alphabet are added the myriad differences of the different alphabets of the world, the *reductio ad absurdum* of testing visual acuity by letters becomes complete.

In contrast with this take the mathematical exactness and constancy of the international standard test. If one always used the same test-card and could have the same letter or letters of equivalent visibility on every line of the card, it would be possible to obtain records of practical accuracy for individual use. As this is not done, when of different visibility, the test-letters fail us even in this practical service. I have a test-card in which the letters are so chosen that the 6-meter line is quite as easy to read, perhaps is more often read correctly at the same distance, than the 7.5-meter line on the same card.

Our test-cards become brown with age, or worn out, and often are not exactly replaceable. I doubt if I could get now, without having them especially made, samples of any of the test-cards used in my first five

Fig. 4.—International test. With normal vision, the direction of the break in the ring can be recognized at 5 meters.

1. Dennett: Tr. Am. Ophth. Soc., 1885, iv, 133.

2. Gebb and Löhlein: Arch. f. Augenh., 1910, lxiii, 69.

years of practice. There are advantages in using different test-cards in testing the two eyes, or in testing the same patient on successive days, and as the different cards have different series of letters to be recognized at the same distance, the practical result is that all records of visual acuity made with test-letters have a very indefinite significance, even in the practice of one surgeon. When it comes to comparing the work of different men, especially in different parts of the world, the practical value of records of such visual acuity is greatly impaired. If the 6-meter line is easier to read than the 7.5-meter line, what do we learn when told that at one visit the patient read most of the 7.5-meter line, and then under treatment he read a week later all of the 6-meter line?

So much for the first objection to test-letters. The second objection is of equal practical importance. It has not been very rare for men required to pass visual tests for a government or railroad service to obtain a copy of the test-card used and commit the letters to memory and thus pass the usual examination without possessing the required visual acuity. Many ingenious contrivances have been devised to prevent such evasions of the test. William Thomson arranged radiating lines of test-letters on a circular card, only one of which lines could be exposed at any one time. Yet a person obtaining a card and memorizing the lines could repeat the smallest letter from his recognition of the largest. Grow³ devised a test-card which he called unlearnable, having sixty letters all of the standard 20-foot size, of which only a single line was exposed in such a way that the observer himself could not know which line was in use except by reading it.

Burch⁴ wrote, "It is astonishing how soon the exact description of a test-card becomes known if many people from the same neighborhood are tested." For the confusion color-test of vermilion letters on a green ground, he advises that the examiner keep paints of the right colors, and paint in new letters for any individual case. The late Dr. George C. Harlan used to tell of a schoolboy who, tested one day with an ordinary test-card of Snellen letters, was able next day to repeat the whole card correctly from memory. The caution sent out with cards for testing schoolchildren, to keep the test where the children will not have a chance to see it, is quite necessary. Probably all of us know without looking at the card the succession of letters on any test-card that we have used much, and the element of memory renders a patient's answers unreliable after a letter has once been recognized, so far as that letter is concerned.

So long as the vision has improved by a change of glasses and progressively smaller or more difficult letters can be read, the ordinary letter or numeral test-card serves its purpose most admirably; but when it is used simply to ascertain the maximum visual acuity, the chance of remembering the letter, instead of seeing it, is a serious drawback. This chance is not confined to letters or numerals. It applies to all cards of test-figures that cannot have their directions or relations changed at will.

Here lies the great advantage of the incomplete square or the broken ring. As was pointed out twenty-five years ago by Landolt, and a few months later independently by myself, if the card on which one or more of these tests are symmetrically placed is simply turned, it becomes impossible for the person tested to

know, except by sight, in what direction the incomplete side is placed. By using a single broken ring or a symmetrical group of them printed on the center of a symmetrical card, the same card can be used for any number of repetitions of the test, without giving any hint of the correct answer, except by vision sufficient to recognize the figure.

This manner of using such a test makes it impossible to have a single card with a whole series of broken rings of different sizes printed on it. But one size can be placed on each card. The same amount of cardboard cut into the proper pieces can be made to furnish an equally complete series. When a large number of persons are to be tested, the best plan is to use a single test of a certain standard size. This is to be looked at first from or beyond the standard of distance. Then the person to be tested should gradually approach the card, until the direction of the break is recognized.

For instance, in testing a class of schoolchildren, the test should be shown to the whole class and its use explained. Then the children should be sent beyond the standard distance and each one made to approach until the break in the ring is recognized. If we take the standard distance of 5 meters, recommended by the International Ophthalmological Congress, and mark it off on the floor in 0.5-meter spaces, or double this distance and mark it in whole meters we can, at a glance, ascertain the visual acuity in tenths. It is true that theoretically the variable distance introduces a minute inaccuracy through varying divergence of the rays from the test object; but this theoretical inaccuracy has no practical importance, and is so extremely minute in comparison with the inaccuracies that we have every day tolerated in connection with the use of test-letters that it may well be disregarded. What is meant by a symmetrical group of broken rings is illustrated in Figure 4.

The rings may be arranged in squares as 1, 4, 9, 16; or any number may be arranged in circular form. I believe that as its advantages are appreciated, the international standard test will come into universal use for the simple testing of visual acuity.

The international test, however, does not so directly help us in the problems of the consulting-room in practically determining and recording the visual acuity obtained by use of test lenses, a very important part of our daily work. In this work series of test-letters arranged in graduated sizes will hold their own against any other method of testing visual acuity that has yet been suggested.

With our ordinary cards of test-letters the practical accuracy of the international standard can be easily attained by the very simple expedient of numbering each line of letters by its equivalent value as compared with the international standard. For instance, instead of calling the 5-meter line a 5-meter line or a 16½-foot line, if it contains some of the more difficult letters, like B or S, number it 1, as expressing full vision according to the international standard. At the same time if half the letters on it can be read by an eye having vision of only 9/10 by the international standard, also indicate this on the card; half the letters equal 9/10, all the letters equal 1. If one or two letters can be recognized by a person having 8/10 vision, that fact might also be indicated; but practically it will usually be best to give only the two values; one value for a certain portion of the letters, as 1/2, and the other the acuity indi-

3. Grow: *Ophthalmology*, 1911, vii, 195.
4. Burch: *Ophthalmoscope*, 1912, x, 320.

cated by reading every letter on the line. In a word, we must standardize our cards of test-letters. When this has been done it is just as easy to read the standard of visual acuity indicated from the card used as to read the old meters or feet printed with each line to indicate the distance at which it was supposed letters of that size should be visible.

With the test-card standardized, we can use any arrangement of letters we choose, and as many different arrangements as we choose. We can employ one card one day and another the next day or the next month, or after twenty years, and still know that the comparisons of visual acuity are accurate. Each nation may test vision by cards suited to its own convenience. Illiterate test-cards of any sort may be employed, and if properly standardized the results will be perfectly comparable.

This matter, simple as it is, is one of great practical and scientific importance. It is entirely worthy of the careful attention of every association of scientific ophthalmologists. To standardize the cards already in use, and to bring the matter properly to the attention of those who publish such cards, it is suggested that this Section appoint a committee, and that every member of this Section should cooperate with that committee to secure the best possible standardization of all test-cards in common use.

Majestic Building.

ABSTRACT OF DISCUSSION

DR. NELSON M. BLACK, Milwaukee, Wis.: As stated by Dr. Jackson the test-letters, even when conforming exactly to the five-minute angle of Snellen, afford the poorest and most inexact standard on which any scientific observations are now based. The statement, "As a help in a subjective measuring of refraction they are superior to any substitute that has been proposed," is also true, but is it not the result of the majority of us having been willing to accept the results of Snellen's observations, and our own fatal tendency to let so-called well-enough alone? Some of the reasons why different letters are visible from different distances may be of interest, and are well covered in the conclusions of Miss Roethlein's most interesting paper, "The Relative Legibility of Different Faces of Printing Types" (Publications of the Clark University Library, Jan. 12, 1912.)

There are other reasons in addition to those given by Dr. Jackson why test-letters should be standardized before they are used as a basis for records of visual acuity. The fact that certain letters of say the 6/VI line are more easily recognized than others at 6 m. frequently gives rise to comments from the patient, such as, "Why am I unable to see all the letters on the line with equal clearness?" and in the absence of the knowledge that the visibility of different letters varies with the distance, gives rise to an idea that perhaps they are not receiving the best correction of their refractive errors. This phase of the subject deserves at least some consideration as well as the factor of the non-uniformity of the results obtained at examinations made at different times and those made by different individuals.

That the letters on the standard test-cards can be easily committed to memory by all who are sufficiently familiar with them lessens their value as a practical test, is a defect which would still exist in the event test-letters were standardized to equal visibility at the same distance. This, however, may easily be overcome by having several cards with the letters arranged in different order and with but one line of letters on each card.

In the use of the international tests some questions arise which may or may not be of importance; for instance, the examinee is informed that the test consists always of the same thing, that is, to designate in which direction the break in the ring exists and that the position of the break in each

ring differs from all the others. Will such knowledge cut down or increase the possible ratio of correct guesses? We all know how frequently, in refraction, patients will call the letter O, G or C or Q or the letter C, O or G or Q. The frequency of this mistake varies with individuals, also with the kind and degree of refractive error. Another question which suggests itself is, Will the fact that the break in the letters C and G is, and always has been, toward the right be a factor in increasing the visibility of the international test-rings in which the break in the circle is toward the right, either above or below the horizontal, as a result of constant association? A third question which should be determined is, What effect on the visibility of the break in the rings will various degrees of astigmatism at various axes have? The ability of the normal eye to distinguish the form of an object depends on: 1, the size of the image received on the retina; 2, the amount of light reflected from the object and its background; 3, the contact between the object and its background.

Dr. Jackson's paper deals largely with the first factor, but there are two remaining factors to be given serious consideration before we can arrive at uniformity in the test for visual acuity.

DR. EDWARD JACKSON, Denver: The idea of standardized letters is this: We must have the letters to do our refraction work. When the refraction work is done, when we have the best lens, we want to record the visual acuity. Now the thing is, from the card we have been using to be able to put down the visual acuity. The way in which this may be done is illustrated by the use of the cards I called attention to yesterday. Instead of giving 6 meters for the first line of letters—that is the distance at which they would be placed in the Snellen scale—this card is prepared for use at 5 meters. The reading of that whole 6-meter line represents 8/10 vision; the reading of the easier letters of the line represents 7/10 vision, as compared with the international standard. After such a card has been used you have the visual acuity according to the international standard, instead of rating V-6/6 or something of that kind. That is the reason for having the standard visual acuity printed on the test-card; it would enable us to standardize our records of visual acuity. With reference to another point of illumination and of background that Dr. Black referred to, the placing of the international broken ring at the end of each line of this card was done with that in view. In comparing the test letters with the international standard we have them on the same card and used by the same light, and if we have taken the proper precautions in standardizing the cards, we will have no difficulty in getting at the true visual acuity.

CONVERGENCE INSUFFICIENCY*

ALEXANDER DUANE, M.D.

NEW YORK

Convergence insufficiency is a frequent anomaly. Probably 8 per cent. of our eye patients show some degree of it, and this proportion would certainly be increased if every patient that presented himself were carefully tested. This statement by no means implies that in all or even a majority of these cases the convergence insufficiency is responsible for the symptoms. On the contrary, in a great many instances convergence insufficiency—especially the accommodative form—seems to cause no trouble whatever. Still it does cause trouble often enough to make it important for us to consider carefully its causation, varieties and treatment.

* Read before the Section on Ophthalmology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

In considering a condition like this it is obviously essential that first of all we should have clear ideas of its nature. We may start, therefore, with a definition and say that convergence insufficiency is a condition the distinctive feature of which is that the eyes converge imperfectly or with difficulty, the disability not being due to impairment in power of the internal recti *per se*. It is, in other words, an anomaly of a coordinate movement of the eyes and not of the eye muscles, and as such it is in all ordinary cases a strictly binocular affection, each eye being equally involved.

DIAGNOSIS OF PURE CONVERGENCE INSUFFICIENCY

A pure case of convergence insufficiency presents the following features:

1. Deviation for distance little or none.
2. Prism divergence (abduction) not excessive.
3. Prism convergence (adduction) subnormal and difficult.
4. Exophoria for near points marked and increasing with approximation of test-object.
5. Convergence near-point abnormally remote.
6. Lateral movements of each eye inward and outward normal in extent and comitant.
7. Diplopia, if present, not increasing to right or left.

8. Convergence reaction of pupil deficient or absent.

These signs deserve a brief consideration.

1. *Deviation for Distance.*—In pure convergence insufficiency there is rarely more than a centrad of exophoria for distance. Not infrequently there is orthophoria, and occasionally even a centrad or so of esophoria. Even when the convergence insufficiency is beginning to be complicated by a divergence excess so that there is more or less exophoria for distance, this is moderate in amount and always much less than the exophoria in near vision.

The tests for distance should be made both with and without the patient's distance-glasses in order to determine the effect that the latter have on the deviation.

2. *Prism Divergence.*—The prism divergence (so-called abduction) for 5 or 6 meters ranges in general from 3 to 8 (in most cases from 4 to 6) centrads. It corresponds, therefore, to the normal. In some cases it may even be subnormal. When the prism divergence is 9 centrads or over, the condition is no longer a pure convergence insufficiency, but is complicated with a divergence excess. There is then usually a more or less considerable degree of exophoria for distance.

3. *Prism Convergence.*—The prism convergence (so-called adduction) for 5 or 6 meters is often low (varying from 6 to 12 or 14 centrads). Low prism convergence in itself means nothing abnormal, since many persons with normal convergence are unable at the start to overcome prisms, base out, of more than 10 or 12 centrads. In such persons, however, it is evident that this inability is due to lack of facility rather than lack of power, and when they once learn, which they do after two or three trials, they go steadily and easily upward, so as ultimately to overcome prisms of 30, 40 and 50 centrads. Moreover, when they can overcome a prism at all, they can hold the images together without difficulty. In convergence insufficiency, on the other hand, it often happens, particularly in the serious and troublesome cases, that the patient who can overcome, say, a 12-centrad prism, can only with difficulty and strain pass from this to

a 14-centrad; and even when he unites the images with the higher prism, he cannot hold them together for more than a moment. In extreme cases of this sort the inability to overcome prisms, base out, is very marked. I remember one instance in which the patient after weeks of faithful trial was unable to advance beyond a 6- or 7-centrad prism. So in cases of convergence paresis (see below) the prism convergence is extremely low or absolutely nil; and it also, of course, is abolished in complex cases in which a well-marked divergent squint has developed; but the latter are never pure cases of convergence insufficiency.

In most cases in which the prism convergence is low and difficult to acquire, it can still be brought to the normal by persistent training, and it is just in such cases, I believe, that training of this sort, when ultimately successful, is most beneficial.

4. *Exophoria for Near Vision.*—The exophoria for 25 cm. ranges from 6 to 30 centrads. Measurements made with the screen, parallax and phorometer usually agree and are pretty constant, provided the test-object is sharply defined (a fine dot is best for the purpose), and provided the patient is directed to fix and focus sharply on it. If these precautions are neglected, the amount of exophoria may vary widely even during the same examination. It often also varies from day to day, the amount depending on the patient's condition and the energy he is able to exert at the time. It will also be modified by the visual acuity and by the strength of the glasses used, and the effect of the latter should be particularly studied, in order to determine how far the deviation is accommodative in origin. In presbyopes a test should always be made with the reading-glass, and the strength of the latter should always be noted.

The exophoria regularly increases as the test-object is brought nearer the eyes. In convergence paresis this increase is particularly marked and uniform. In fact, in order to make the diagnosis of paresis, we have to make our near tests both beyond and within the usual 25-cm. distance, for instance, also at 1 meter, 50 cm. and 10 cm. (see below, in the discussion of convergence paresis).

However great the exophoria for near vision, in pure cases of convergence insufficiency it is habitually overcome at the ordinary reading-distance, provided both eyes can see the object of fixation. The patient, that is, has ordinarily at near points an exophoria and not a squint, although he may, and often does have momentary failure of binocular fixation with consequent double vision and confusion. It is only when the insufficiency is complicated with other factors (consecutive divergence excess, secondary weakening of the interni) that a constant squint for near points develops.¹

5. *Convergence Near-Point.*—The convergence near-point (Pc) is abnormally remote. The normal position of the convergence near-point, as determined by a number of measurements, is in adults from 5 to 9 cm.,² and in children 4.5 to 8 cm.³ from the base-line connecting the centers of the two eyes. It can be quite precisely measured as follows: The patient's glasses, or in lieu of these a trial-frame or spectacle-

1. Even when complicated with a marked divergence excess, so that the deviation is as high as 50 centrads, the patient may at times get binocular single vision. But in such cases the original condition is always probably a divergence excess, the convergence insufficiency being secondary and of recent development.

2. Indicating an actual convergence of from 38 to 62 degrees.

3. Indicating an actual convergence of from 45 to 65 degrees.

frame, is placed on the patient's nose and is used as a reference plane which is adjusted so as to be just 11.5 mm.⁴ in front of the corneal apex when the eyes are directed straight ahead. The apex of a millimeter rule is placed against the point at which the reference plane crosses the nose, and the rule itself is held perpendicular to the plane, so as to lie strictly in the midline. Along this rule the test-object, which consists of a pin with a white head 2 mm. in diameter, or a minute dot on a card, is carried straight toward the patient's nose, the patient all the time being exhorted to converge on it as sharply as he can. The moment the object doubles insuperably, or the moment one of the patient's eyes is seen to diverge, the distance of the object from the reference plane is measured. If to this distance 2.5 cm. be added, the result will be very nearly the true distance of the convergence near-point from the intercentral base-line. If the latter distance (PcB) is beyond 8 cm. it denotes some weakness of convergence, and if beyond 10 cm. a well-marked insufficiency. Or we may say that the patient has a convergence insufficiency if his *convergence index*⁵ falls below 30.

It is understood that in making this test the patient should try as hard as he can to converge on the test-object and to fuse the images as soon as the object tends to double.

In simple convergence insufficiency the convergence near-point is *absolute*, that is, the patient brings the eyes together so that both are directed at the test-object. When there is exotropia, only one eye is directed at the object and converges on it as it is approximated. In that case the other eye may make no attempt to converge at all, so that as fast as its fellow eye comes in, it goes out. Or, it also may make at least an attempt to converge and, although never actually directed at the test-object, may follow it in its movement toward the eye down to a certain point (*relative* convergence near-point) and then suddenly give up the effort and diverge.

The closer the relative near-point of convergence is, the greater we judge the patient's converging power to be, and the more we can rely on it in supplementing the effect of exercise or of operation.

When the patient has a considerable vertical deviation, his converging power may appear to be poor, when really it is quite good, for when the test-object is brought toward the eyes, he sees two images which he cannot bring together because they are on different levels. As he cannot unite them he makes no attempt to converge. In that case the dot used as a test-object should be replaced by a vertical line. The patient will converge on this, because when he does so the two images will unite, even if on different levels, since the bottom of one will join with the top of the other. On such an object a patient will be able to converge sharply, even when for the dot he apparently had very little converging power.

4. The distance is 10.5 mm. if the eye is quite myopic, 12.5 mm. if the eye is highly hyperopic.

5. The convergence index (Ci) = $100 \times \frac{1}{2}$ interpupillary distance

PcB

Ci ordinarily ranges from 35 to 50, although it sometimes equals 55 and may even (especially in children) run up to 60 or 63. When Ci is between 15 and 59, that is, for all values commonly encountered in both normal and abnormal cases, the relation holds that $C = Ci + 3^\circ$, where C is the corresponding convergence of the eyes in degrees. For higher values of Ci the following relations obtain:

Ci	C	Ci	C
60-63.....Ci + 2°	75-77.....Ci - 2°		
64-67.....Ci + 1°	78-80.....Ci - 3°		
68-71.....Ci	81-83.....Ci - 4°		
72-74.....Ci - 1°	84-85.....Ci - 5°		

6. *Lateral Movements of the Eyes.*—In a pure convergence insufficiency, the inward and outward rotations of each eye, when moving parallel with its fellow, are normal in extent and comitant. This is found both in monocular and in binocular testing. An eye, for example, which, in attempting to converge with its fellow, halts when its corneal margin is 2 or 3 mm. from the caruncle, will, when tested with the perimeter or tropometer, rotate 45 or 50 degrees inward, and then, following the other eye as the latter moves outward, will turn in fully to the caruncle. Moreover, the movements are comitant, one eye moving as fast as the other without wavering or lagging on the one hand, or overshooting, on the other.

7. *Diplopia.*—Diplopia if present does not increase as the eyes are turned to the right or left. Owing to the natural tendency of the eyes to diverge when raised and to converge when lowered, the crossed diplopia caused by a convergence insufficiency tends to increase in looking up and to diminish in looking down. In slight cases of convergence insufficiency it may be present only in the upper field. Owing to the fact that the diplopia is caused by the inability of the eyes to converge properly, it naturally increases as more and more call is made on the converging power, that is, as the test-object is brought nearer the eyes. In a convergence paresis, this increase is particularly striking and takes place with almost mathematical regularity from distance to near, beginning to be observable at 20 feet or more from the eyes.

8. *Pupillary Signs.*—In cases of marked convergence insufficiency with remote convergence near-point, and particularly in cases of convergence paresis, the convergence reaction of the pupil is diminished or absent. In ordinary cases if we bring an object toward the eyes and urge the patient to fix sharply on it, the pupils contract as the eyes converge. The moment he gives up the effort of convergence and the one eye flies out, the pupils dilate. The more remote the convergence near-point, the sooner this will occur and the less marked will be the initial contraction of the pupil. In great weakness or in actual paresis of convergence there may be no initial contraction of the pupils at all. In this case if the reaction to light is present we have the inverse of the Argyll Robertson pupil.

DIFFERENTIATION FROM OTHER FORMS OF EXOPHORIA

The two chief conditions from which a convergence insufficiency is to be differentiated are divergence excess and insufficiency of an adductor.

DIFFERENTIATION OF CONVERGENCE INSUFFICIENCY AND DIVERGENCE EXCESS

CONVERGENCE INSUFFICIENCY	DIVERGENCE EXCESS
Exophoria for distance slight (only one or two centads).	Exophoria for distance marked (from 5 to 30 or more centads).
Exophoria for near marked (8 to 30 centads).	Exophoria for near moderate (much less than for distance) may be almost nil.
Prism divergence not excessive (4 to 8 centads).	Prism divergence excessive (10 to 30 centads).
Prism convergence deficient and difficult to increase by exercise.	Prism convergence normal or readily brought to normal after two or three attempts.
Convergence near-point remote (over 9 cm. from intercentral base line).	Convergence near-point normal.
Crossed diplopia, if present, marked for near points and increasing as object is brought toward eyes.	Crossed diplopia if present, marked for distance. Usually none for near.

In both, rotations of eyes inward and outward in performing parallel movements normal and comitant; crossed diplopia, if present, not increasing to right or left, but increasing somewhat in looking up and decreasing somewhat in looking down.

Divergence Excess.—A considerable number of cases of exophoria, probably a third, in fact, of all the cases that we see, are due primarily to what I call divergence excess. This condition is differentiated from a convergence insufficiency by the accompanying signs given in parallel columns.

Insufficiency of an Adductor.—From insufficiency of an adductor (internal rectus, superior and inferior recti), convergence insufficiency is differentiated by the fact that in the former condition either the power of movement of the affected eye inward is obviously impaired, or at all events the exophoria and the crossed diplopia, if present, increase definitely as the eyes are carried to one side or the other.⁶

MIXED AND SPECIAL FORMS

In many cases a convergence insufficiency is combined with other conditions, and sometimes the picture is so complicated as to render the diagnosis difficult. The most common combinations are:

1. *Convergence Insufficiency with Divergence Excess.*—This combination is very frequent. In fact, in the regular development of an ordinary divergent squint, what generally takes place is that either a primary convergence insufficiency has superadded to it a secondary divergence excess, or vice versa. In the former case, we see first an exophoria for near with normal relations for distance, later a squint for near combined with an exophoria for distances, and finally a squint for both distance and near with total absence of converging power. When the divergence excess is the primary condition, we have first an exophoria for distance with normal relations for near. This condition may last indefinitely or at least for many years without change. Then there develops an exophoria for near also, and a squint for distance, and ultimately a squint at all ranges, with, however, often at least partial retention of converging power. The last-mentioned is shown by the presence of a relative near-point of convergence. Whichever condition is the primary one, the final picture presented by the combined conditions is then a squint marked for both distance and near, and great, though by no means always total, loss of converging power.

2. *Convergence Insufficiency with Secondary Weakness of Interni.*—Secondary weakness of the interni often develops in cases of divergent squint of long standing; that is, as a result of a continued insufficiency of convergence combined with a divergence excess. In this case the power of rotation inward in making parallel movements of the eyes to right and left is obviously diminished.

3. *Convergence Insufficiency with Insufficiency of the Elevators or Depressors.*—This condition, which is manifested by a vertical deviation, increasing characteristically in some special quarter of the field of fixation, is not infrequent. In some cases of the sort the convergence insufficiency is more apparent than real (see below in the consideration of etiology).

4. *Convergence Insufficiency with Divergence Insufficiency.*—This rare and troublesome condition is marked by an exophoria for distance with very low prism divergence or actual homonymous diplopia for distance, and by marked exophoria for near with remote near-point of convergence. In some extreme cases there is an actual paresis of both divergence and convergence (see below in the section on convergence paresis).

5. *Anomalous Cases.*—Cases of rather peculiar physiognomy are those in which (a) there is a marked exophoria for near (10 or 12 centrad) with normal relations for distance and with normal convergence near-point, and (b) those with very slight exophoria for near but with remote convergence near-point. The former are perhaps to be explained as due to a slight weakness of the interni *per se*, and the latter as an ordinary convergence insufficiency, in which the patient by special effort at times overcomes the deviation.

ETIOLOGY

Convergence insufficiency is either primary or secondary.

A. *Primary Convergence Insufficiency.*—This may be either accommodative or non-accommodative.

1. *Accommodative convergence insufficiency* is the form in which the patient converges insufficiently because he accommodates insufficiently. This form is observed, first, in uncorrected myopes who, as they do not have to accommodate in looking at near-points, so do not converge either; second, in corrected presbyopes and hyperopes who, when they put on convex glasses, find themselves enabled to read without exerting their usual quantum of accommodation and, as they let their accommodation relax, relax their convergence also.

In all these cases of accommodative convergence insufficiency it is evident that the patient really has full power of accommodation, but, owing to refractive conditions of one kind or another, he exerts only part of it. As he puts only a portion of his available force into his accommodative work, he also puts only a portion into the work of converging and hence converges imperfectly. But there is another class of cases, rather frequent, in which the accommodation is really subnormal, and the patient works it to its limit, putting into it all the nerve-power at his command. How he will converge in this case will depend on the cause of the weak accommodation. There are two possibilities. Either the patient's neuromuscular accommodative apparatus is defective and his nerve-power is normal, in which case he makes a tremendous effort and nevertheless accomplishes very little, or his accommodative apparatus is normal but the nerve-power supplied to it is inhibited in some way, in which case he makes but little effort and therefore accomplishes but little. In the former case there is overstimulation, in the latter case understimulation of the accommodative apparatus and hence also of the converging apparatus. If the converging apparatus is normal, the patient should in the first case have a convergence excess, and in the second case a convergence insufficiency as the result of a genuine accommodative weakness. Examples of these two kinds of association do, in fact, occur, but are not very common, so that accommodative convergence insufficiency is apparently not often due to accommodative weakness of central origin. It more frequently happens that the two conditions, instead of being dependent one on the other, occur simultaneously, both being due independently to the same cause. In this case, of course, the convergence insufficiency is non-accommodative in origin.

Akin to accommodative convergence insufficiency is what we may call the *visual* form in which, owing to indistinctness of vision in one or both eyes or to incorrigible vertical diplopia, the patient has little impulse to converge. This is found in uncorrected presbyopia and in hyperopia of high degree; in anisometropia

6. Increase from the midpoint to both sides if both interni are weak.

(very common); in poor vision due to opacities in media and also in absolute blindness of one eye, and in hyperphoria or other muscular anomalies which render fusion difficult. In cases of this sort the convergence insufficiency is usually spurious, at least at the outset. The patient, that is, can converge perfectly, but has no inducement to do so because the diplopia produced by the failure to converge is no more confusing than is the patient's vision when he converges well and superposes the two visual images. In other words—and this holds for most of the cases of the accommodative form too—the condition at the beginning is rather a convergence disuse than a convergence insufficiency. Later, however, continued disuse develops an actual insufficiency.

2. The *non-accommodative* form comprises about 60 per cent. of all cases of primary convergence insufficiency. It includes all those cases in which the refraction and accommodation cannot in any way be held accountable for the genesis of the motor anomaly. This is the case in patients who have low degrees of hypermetropia and astigmatism with equal refraction and with good vision in both eyes; also in patients who, though myopic, have been wearing their myopic correction for a long time, so that they are using their accommodation quite like emmetropes. In all these cases it is noted that continuous wearing of the proper refractive correction does not affect the muscular deviation except possibly to increase it. In a true accommodative convergence insufficiency, on the other hand, the deviation is diminished or even abolished altogether by the continuous use of the right glasses.

Non-accommodative convergence insufficiency is due to (a) conditions causing general nervous or systemic depression (neurasthenia, hysteria, anemia, convalescence from exhausting illness, and the like); (b) nasal obstruction (quite common), and (c) some unknown cause acting in persons whose muscular power and coordination otherwise seem normal. The more serious and inveterate cases, and particularly those that approximate to a convergence paresis in character, are perhaps due to a localized lesion, congenital or acquired, of the central nervous system (see below, section on convergence paresis).

As already noted, a convergence insufficiency, even when non-accommodative, may be associated with a weakness of accommodation which, like the insufficiency itself, is of central origin, the two being due independently to the same cause.

3. *Combined Accommodative and Non-Accommodative Forms.*—These mixed forms are not uncommon. Thus a convergence insufficiency, itself non-accommodative, may be increased and its symptoms may be intensified by the introduction of an accommodative element. This happens, for example, when we give a hyperope or a presbyope who already has a convergence insufficiency, too strong a glass for reading.

B. *Secondary Convergence Insufficiency.*—When a divergence excess has lasted a long time, a secondary convergence insufficiency often develops, producing the combined form of deviation, the characters of which have been noted. (See remarks on "Course," below.)

CONVERGENCE PARESIS

No absolute line of demarcation distinguishes a convergence insufficiency from a convergence paresis. In fact, the extreme form of convergence insufficiency that we see in a well-marked periodic divergent squint is really a convergence paresis more or less obscured

by complicating conditions. The term "convergence paresis," however, is usually applied to a condition often sudden in development and evidently due to localized lesion or functional disturbance of the nerve centers, marked by the following features:

1. In far distance (points beyond 20 or sometimes beyond 50 feet), little or no deviation.

2. The moment an attempt at convergence is made, that is, as soon as the patient tries to follow an object brought from the 20-foot distance toward the eyes, exophoria and crossed diplopia set in and increase *pari passu* as the object is approximated. The increase takes place with almost mathematical regularity.

3. The diplopia once evident is almost or quite insuperable. Thus, when even it is so small that it requires only a 2- or 3-centrad prism to correct it, the patient is usually quite unable to correct it by voluntary effort. So, too, at a distance at which he normally sees single, he is quite unable to overcome even a 2- or 3-centrad prism, base out.

4. No attempt is made at convergence. When an object is carried toward the eyes, one turns toward it and the other turns off, *pari passu*. In a pure convergence insufficiency, however great, there is usually at least an attempt at convergence.

5. Just as in ordinary convergence insufficiency, so also in convergence paresis the lateral movements of the eyes are unaffected, each eye as it moves with its fellow to right or left rotating quite normally inward. So also the crossed diplopia, taken at any given distance, does not increase as the eyes are carried to the right or left. In other words, we are not dealing here with any paresis of the interni *per se*.

6. The convergence reaction of the pupil is usually absent.

Convergence paresis is rather rare. Still rarer is its combination with a paresis of divergence. In this condition, there is a single vision only at one definite point. Beyond this there is homonymous diplopia, within this crossed diplopia. Looking at an object situated at the point itself, the patient cannot overcome a prism, however weak, either base out or base in. It seems, in fact, as if his eyes were fixed immovably on a single point. But when it comes to making lateral or up and down movements, each eye moves as freely as usual and always in harmony with the other.

Convergence paresis may also be associated with paralysis of up-and-down movements of the eyes. It is at times, too, accompanied by paresis of accommodation, the lesions in this case being strictly coordinate; that is, they occur simultaneously as the result of the same cause and are in no sense dependent the one on the other. The picture then presented is very striking.

Convergence paresis is doubtless due to some lesion of the central nervous system. It occurs in multiple sclerosis (in 3 per cent. of the cases according to Uhthoff) and occasionally in tabes, and in isolated cases it is the result of traumatism, hysteria, tumor, hemorrhage and developmental disorders arising from affections of the ductless glands. It is also found as a congenital anomaly in most cases of the peculiar syndrome marked by paralysis of the external rectus, restriction of power of the internal rectus and retraction movements of the eyes.

In a case of mine which was associated with a marked paresis of accommodation, the voluntary dissociation of the eyes produced by prolonged work with the microscope seemed to be the starting-point of the trouble. In some cases the etiology is quite obscure.

COURSE

An accommodative convergence insufficiency of the ordinary type is, as I have noted, at the outset simply a convergence disuse. That is, the converging power is normally strong but is not used to its full extent. After a time, owing to this continued disuse, the converging power becomes actually subnormal. When this process is once initiated, there is a tendency, although by no means an invariable tendency, toward increase.

If it increase to a considerable point and is long maintained, it is then regularly followed by a divergence excess. Similarly, a divergence excess which has lasted a long time is likely to be followed by a convergence insufficiency. Thus result the combined forms (see above "Mixed and Special Forms"), which constitute the ordinary form of a fully developed divergent squint. A divergent squint, in other words, usually develops in one of the two following ways:

1. An accommodative or at all events a visual convergence insufficiency develops out of a convergence disuse. This at first is a heterophoria, which is marked for near points only. Gradually this increases by the superadding of a divergence excess, and now there is a heterophoria for a distance with a divergent squint for near (direct periodic squint). The deviation at both distances increases until ultimately there is a squint both for distance and near (continuous squint), but more marked for near.

2. A divergence excess, which produces a heterophoria marked for distance and but slight for near, which may last unchanged for years, ultimately increases by the superadding of a convergence insufficiency. There is now a divergent squint for distance and a heterophoria for near (inverse periodic squint). These increase until ultimately there is a squint for both distance and near (continuous squint), more marked, however, for distance than for near.

In both cases, a further change that takes place after a while is a weakening of the interni (hitherto normal) and a contracture or hypertrophy of the externi. The inward rotations are then no longer normal and the deviation becomes greater still.

The course of a non-accommodative convergence insufficiency—and the same is true of a convergence paresis—depends on its causation. If due to a temporary condition, the insufficiency or the paresis will clear up; otherwise it may remain unchanged for years or in some cases gradually increase. A non-accommodative convergence insufficiency may thus also give rise to a divergent squint.

SYMPTOMS

The symptoms of convergence insufficiency are diplopia (with accompanying confusion and vertigo), asthenopia, eyecache, headache, and sometimes more remote reflex symptoms.

Diplopia, although it can almost always be elicited, is rarely a subject of spontaneous complaint except in convergence paresis, when it is often very distressing. Confusion (especially in reading) and vertigo may occur, but are not common except in extreme cases of insufficiency or cases of actual convergence paresis.

Asthenopia is a common symptom, and often is associated with burning and irritation of the eyes (asthenopia irritans) or with eyecache (asthenopia dolens). The asthenopia is sometimes extreme and incapacitating. It is often aggravated by the use of

convex glasses, because with them the patient not only tends to relax his accommodation and hence increases his convergence insufficiency, but also brings objects close and so puts more strain on his convergence. Sometimes, in fact, the asthenopia is so great that the patient cannot wear the proper glasses at all.

Headache is not a very common symptom, nor are reflex symptoms very often encountered—not so often, indeed, as in other muscular anomalies. Of course when squint has developed, the deformity due to it constitutes for the patient a symptom of considerable moment, and in convergence paresis and in convergence insufficiency due to general conditions we have to reckon with the symptoms arising from the causal lesion. So, too, we have to reckon with the asthenopic symptoms due to the associated insufficiency of accommodation when this is present. These may be difficult to distinguish from the symptoms of convergence insufficiency itself.

In a large proportion of cases of convergence insufficiency there are no symptoms whatever that can be referred to the motor anomaly itself, that is, that are not relieved simply by treatment of the attendant conditions (refractive errors, etc.).

TREATMENT

The measures available for treating a case of convergence insufficiency are:

1. Correction of the refraction.
2. Correction of exciting causes other than refractive errors.
3. Practice in converging on an approximating point and with prisms, base out.
4. Practice with the amblyoscope, stereoscope and bar-reading.
5. Practice in the recognition of diplopia with the aid of the red glass, etc.
6. Prisms for constant wear.
7. Operation.

1. In a case of convergence insufficiency the first demand of treatment is to correct the *refraction* with scrupulous care. By so doing we remove any accommodative or visual element which may aid to produce the insufficiency, and thus in a moderate proportion of cases relieve or at least diminish the tendency to deviation. In a much larger proportion of cases, the correction of the refraction, while not producing much effect on the deviation itself, does relieve the symptoms.

A convergence insufficiency associated with hyperopia is sometimes aggravated by the full correction of the refractive error. In such cases we may have to undercorrect the hyperopia by an amount which will vary with the conditions and symptoms present in the given case, but which in general will have to be determined experimentally.

In presbyopia associated with convergence insufficiency it is particularly important not to add too strong a glass for reading, since with such a glass the patient will have to bring objects too close and thus impose too great a strain on the already subnormal convergence. Neglect of this precaution is a frequent cause of trouble in giving glasses to presbyopes, especially in the early stages of presbyopia.

As in other muscular conditions, so also especially in convergence insufficiency, correction of the refraction should be the first means used, and until its efficacy has been tested by long and persistent trial, other

treatment should not generally be employed. Otherwise we shall fail to differentiate between the symptoms due to the refractive error and those due to the muscular trouble. By eliminating one set of symptoms at a time, and the one, moreover, that is usually of most significance to the patient, we shall be surer of our diagnosis and more likely to give ultimate relief. It need scarcely be added that the earlier in a case the refractive treatment can be applied the better the result we may expect.

2. In non-accommodative convergence insufficiency and particularly in convergence paresis, the exciting cause (neurasthenia, hysteria, nasal disease, organic disease of the nervous system) must be sought out and treated. In cases the etiology of which is not evident, tonics, open-air exercise and the restriction of near work for a season are often indicated.

3. Exercising the convergence by simply making the patient fix sharply with both eyes a dot brought steadily up toward the eyes or by practice with prisms, base out, is of service both in accommodative and in non-accommodative convergence insufficiency. I have 'elsewhere' laid down precise rules for what I believe to be the best method of making the practice. In general I think it important that in simple convergence insufficiency, exercise with converging prisms should be employed with the test-object at the reading distance only, while if there is an associated divergence excess the exercise should be done with the object both at 20 feet and at near. These exercises seem to me to succeed particularly well when there is an associated weakness of accommodation; the latter is also thereby stimulated.

4. The use of prisms for exercising the convergence presupposes ability to recognize diplopia and to fuse double images. If the patient is deficient in either regard, we shall secure better results with the amblyoscope. The way to use this is, first, to get the patient habituated to seeing with the two eyes together, that is, to set the instrument in such a way that he clearly makes out two distinct images. The second step is to habituate the patient to seeing with both eyes when the images are brought close together, and finally to adjust the tubes so that the two images are superimposed and actually fused. The third step is to make the patient practice convergence after the images are thus fused, that is, to urge him to swing the tubes toward each other while still maintaining fusion. The successful carrying out of these different stages of the practice may take weeks or months.

For the proper carrying out of this practice, the amblyoscope should have a suitably graduated arc, so as to measure the position of the tubes and register the amount gained by exercise, and also a vertical adjustment to correct the hyperphoria that is not infrequently present.

Fusion may also be exercised usefully with the stereoscope and with bar-reading.

5. Another way, besides the amblyoscope, of getting the patient to recognize the fact that he sees double and to pave the way to the use of converging prisms, is to separate the images widely by prisms, or to make the images dissimilar by using a red glass before one eye and a green glass before the other. Systematic exercises at home of this sort may usefully precede exercises with prisms, base out.

6. The use of prisms, base in, to correct the deviation is in my belief a procedure to be condemned. Affording a temporary relief, it has seemed to me that in most cases such prisms ultimately increase the deviation and the symptoms, too. On the other hand, the correction of a coexistent hyperphoria by prisms, base up or down, may afford considerable relief to the symptoms and make the lateral deviation much more manageable by ordinary means.

7. Operation should not be done unless all other means have been thoroughly tried and have failed and unless also the symptoms are severe and likely to be permanent. In a simple convergence insufficiency, advancement or tucking of the internal recti is indicated. It may or may not be combined with tenotomy of the external rectus, but if we are dealing with a simple convergence insufficiency, the tenotomy should not involve the lateral attachments of the tendon and should be done to such an extent only as to relax the strain on the advanced muscle. If there is well-marked divergence excess, free tenotomy of the externus should be combined with the advancement of the internus.

It is best to operate on one eye and from four to six weeks later operate on the other if necessary.

If there is a considerable vertical deviation this should in general be relieved by operation before any attempt is made to operate for the lateral displacement. Otherwise the lateral displacement is liable to recur, and on the other hand, if the vertical deviation is corrected first, it may happen that the lateral deviation may not need correction at all.

139 East Thirty-Seventh Street.

ABSTRACT OF DISCUSSION

DR. WILLIAM N. SOUTER, Portsmouth, N. H.: I would not use the centrad in prism measurement. I have no criticism to make of the centrad in itself, but the prisms in our trial cases and those kept in stock by opticians are not made on the centrad scale; and since I know of no advantage which the centrad has over the prism diopter, I think it is better to use the latter, the generally adopted unit. It is true that the centrad and the prism diopter are so nearly equal in value that no error is ordinarily made by designating in centrad prisms which are manufactured on the diopter scale, but in the very strong prisms an amount of error is ignored, which, though not serious, is yet not in accord with Dr. Duane's usual accuracy. A prism of 50 prism diopters corresponds to 46 centrads. My second point of disagreement with Dr. Duane is as to the amount of convergence which is to be regarded as normal. He makes a diagnosis of convergence insufficiency if the person cannot converge to a point 9 cm. from the intercentral base line, or, on an average, about $2\frac{1}{2}$ inches from the root of the nose. I do not think so great an amount of convergence is required for comfortable use of the eyes in ordinary near work. I should hesitate to ascribe to convergence insufficiency any symptoms which might occur in a person who could converge to a point 12 cm. from the intercentral line, 4 inches from the root of the nose. Thirdly, I do not believe that prism exercises or convergence exercises are a rational procedure. I say this, though I am aware that I am in this respect at variance with the majority of ophthalmologists. I believe that, aside from the psychic effect, nothing whatever is gained by this method. I have reached this conclusion partly from my own early experience, partly from the results which I have seen in patients who have undergone this kind of treatment under the direction of competent advocates of such exercises, and partly from my conviction that it is unreasonable to expect these exercises to accomplish what cannot be accomplished by the normal stimulus afforded by the ordinary use of the eyes in near work. Finally, I believe

that prisms, bases in, are of great value for permanent wear in cases of uncomplicated convergence insufficiency. In many of these cases there is some innate peculiarity which renders convergence difficult, and the slight assistance afforded by the prisms is sufficient for comfortable use of the eyes. I have patients who have been wearing such prisms for many years with permanent relief.

DR. FRANCIS VALK, New York: I wish to speak only with reference to when and how to operate in these cases of what I call exophoria or the convergence insufficiency of Dr. Duane. I fully agree with him concerning the treatment of these cases—the only ones, in my opinion, suitable for prism exercise—but when we have passed that stage we must consider an operation. Dr. Duane has placed this as the last procedure; but we see these cases after all other means have failed; then why not operate at once? If we have a low degree of exophoria they may be improved by other means, but if we have an exophoria of more than 3 degrees it seems to me that all these attempts to improve the motive power of the interni will be useless, and that operation must come. If that is correct, and all tests, both subjective and objective, show a high degree, then operate. I plead for early operation because I think the day of tenotomy has passed, and when we can do a simple and effective operation that always gives relief, never gives an overcorrection, and can be performed under cocaine, that procedure which is now offered to the profession in more than ten different methods, should be the operation of choice. I refer to the well-known operation of shortening the tendon of the weak muscle. Furthermore, Dr. Duane says, "Operate on one eye and in three or four weeks operate on the other." Which eye, however, shall be operated on first? This is to me a very serious and important question, as I have seen many failures from tenotomy. If you operate on both you may get the right one, but is that correct? Is the fault equally present in each eye? Hence, if we can place our weak muscle in insufficiency or in excess, is it not essential to shorten the weak muscle before any attempts to do a tenotomy? I have followed this rule for many years and seldom do more than one operation, when I follow the readings of the tropometer; and, as Howe says, this instrument is the keynote and indicator of all operations on the muscles of the eye.

DR. D. W. WELLS, Boston: With regard to the treatment of insufficiency, under Head 4 as given by Dr. Duane, I should like to make a plea for the more constant use of the stereoscope. Dr. Duane has said that many cases could not be well trained by prisms, because the patients do not quickly recognize diplopia. It seems to me, therefore, the logical procedure would be to carry on some course of educative treatment which would teach the patient to recognize diplopia, and nothing is better for this than to train the fusion faculty. Simple testing with the stereoscopic charts will show that most of these patients tend to suppress one eye more quickly than the other as soon as the test-letters become small. Now the use of the stereoscope with charts which will increase the patient's fusion faculty is one of the best means of teaching him to overcome this insufficiency. The power of a muscle, it seems to me, depends not alone on its size, but also on the innervation which goes to the muscle, and this depends on the development of the fusion faculty, and varies in different individuals. Therefore my plea is for the development of the fusion faculty by means of the stereoscope and also by constant bar and control reading which Dr. Duane simply mentioned. This can be carried out quite systematically and the patient himself can see the value and advantage of properly using his fusion faculty.

DR. EDWARD JACKSON, Denver: One or two points have been raised that deserve emphasis. Of treatment, Dr. Duane puts first and emphasizes correction of errors of refraction. Errors of refraction are a more frequent cause of some symptoms of convergence insufficiency than is convergence insufficiency itself; but real convergence insufficiency is probably caused by efforts to overcome errors of refraction. We all understand how myopia, preventing the normal use of accommodation, may lead to convergence insufficiency; but other errors of refraction—astigmatism, and particularly

anisometropia—may disturb the coordination of ocular movements; and, as Dr. Duane points out, this is the essential fault in convergence insufficiency. I use prism exercises very little. I see many cases in which, I think, they are used foolishly and uselessly. Yet as this trouble is a disturbance of coordination, we may sometimes bring about better coordination by breaking up the old habits; and I know of no more direct and effective means of doing this and improving the coordination of the ocular movements, than by exercising them with prisms as has been recommended. The centrad departs from the prism diopter, when the prism diopter departs from conforming to the requirements of a scientific unit. As long as ten prism diopters are ten times one, the two go together; but when the 50 prism diopters are only 46 times the one prism diopter, then the prism diopter departs from being a scientific unit and from the centrad. In practical use I never saw a trial case in which the prisms ran above 30 centrads; but when we get up to the higher degrees of deviation, 60, 80 or more centrads, then the prism diopter is a very inferior unit of deviation.

DR. MARK D. STEVENSON, Akron, Ohio: For a number of years I have been examining for insufficiency, in all cases; some of it is frequently found. The practical point is that we should be careful in determining the distance in selecting lenses for close work for such patients. Unless the vocation demands a special near point, we should give lenses with which the patient can see at a fairly good distance. Strong lenses, making him read at a very close distance, especially in people with great pupillary distance, give added work for the adductors. Often the last straw is what counts and if only a little assistance is given the patient is relieved. I found also in a series of tests, made years ago, in examining in different positions in the field with a small point of light and Maddox rod, which of course is not perfectly exact, that the insufficiency was different in degree straight ahead or to one or the other side. I found I could relieve some of these patients by causing them to hold the reading-matter to one side. They could converge better to one side than to the other, just as we have trained ourselves in school to have the books to one side. Some of these patients are probably slightly parietic from various toxemias, the cure of which will give relief. In anisometropia it is often important that the patient hold the reading-matter in a particular place, to one side, or up or down or with the head held in a particular position. We should all realize the importance of muscle training; it does not matter that before muscle training we have for example 9 degrees of lack of balance and afterward the same. If we have stronger muscles to overcome the insufficiency the patient may be rewarded with relief from symptoms. The muscle exercises may need to be repeated, but if it gives a patient months of ease and relief, that is the purpose of our calling.

DR. GEORGE H. PRICE, Nashville: The definition of the condition given by Dr. Duane in the second paragraph of his paper reduces it to one ordinarily known as asthenopia, and the question is as to the best method by which we can combat these symptoms of insufficiency. I was struck by the suggestion of Dr. Stevenson that when some of these patients held the book in a certain position they would be relieved in great measure of the discomfort of the insufficiency. This is a point of great significance. When we have insufficiency of the internal recti we are dealing with a muscle not sufficient in strength to overcome the opposing muscle, and this is because in every individual the musculature varies. The innervation of the internus is almost from the same source practically as that of the superior and inferior recti and the inferior oblique and the coordinate muscles of accommodation. Therefore that has a great deal to do with it. If you have bad accommodation then you have the complication of the deficiency of the internal recti, or of the involvement of the ciliary muscle. All these things must be considered in correcting the vision. The amount of accommodation is indicated by the patient. If all the muscles of the eye are low in their muscular strength, then it would be impossible to go ahead and strengthen one pair of muscles. It would not be desirable; but we would exercise all of them. The simplest

method of doing that is by the ceiling-to-floor and wall-to-wall method. If the patient has low accommodation and insufficiency of the internal recti, a little exophoria and considerable hypermetropia, I know he will have trouble.

DR. OSCAR WILKINSON, Washington, D. C.: Exophoria for near is a normal condition. I have for the past three years, in all presbyopic cases, examined for near and I would say that at least 90 per cent. will have exophoria for near of at least 3 to 5 degrees. So I do not think we should assert that exophoria of 4 or 5 degrees is abnormal. It does not really demand any attention. I would also like to concur with Dr. Duane with regard to the slight changes that the correction of the refractive error makes on these muscular defects. I thought at one time it probably had a great deal to do with that, but after studying a great many cases after the glasses had been worn I find there is practically no change in the muscular balance due to the correction. He also notes another thing which I have noticed, that right hyperphoria is much more frequent than left. In the cases which Dr. Duane called paresis I have found electricity to have a markedly beneficial effect, and I think we are neglecting a valuable therapeutic agent if we do not use it in recent cases. I also use tincture of *nux vomica* internally.

DR. ALEXANDER DUANE, New York: Dr. Souter thinks I have placed the convergence near point too close. I should have thought so too, had I not made a series of measurements which seem to show that the distances ordinarily assigned are too remote. A convergence near point beyond 9 or, at any rate, 10 cm. from the base line connecting the centers of the two eyes I consider too remote, and if constantly present indicates a convergence insufficiency. With regard to exercise with prisms, base out, in convergence insufficiency, I think a good deal depends on how they are used. If the exercise is made with the object at 20 feet we may not only do no good but may do harm. I am a little more chary of doing operations than Dr. Valk, and yet I recognize the good results from his tucking operations. He asks how we are to determine which eye to operate on first. I should select the eye which in the act of converging regularly diverges and which also shows, as it is apt to do in cases requiring operation, a demonstrable secondary weakness of the internal rectus. I agree with Dr. Wells as to the value of the stereoscope and bar reading, and I find his stereoscopic card very valuable. Dr. Stevenson makes a point about convergence insufficiency in presbyopia. He will find on referring to my article that he and I are in substantial agreement—that is, if I understand him aright.

SUMMARY OF RESEARCH STUDIES IN PSORIASIS*

JAY F. SCHAMBERG, M.D.

Director of the Research; Professor of Skin Diseases, Philadelphia Polyclinic and College for Graduates in Medicine

A. I. RINGER, M.D.

Assistant Professor of Physiologic Chemistry, University of Pennsylvania, Department of Medicine

G. W. RAIZISS, Ph.D.

Associate Professor of Physiologic Chemistry, Philadelphia Polyclinic and College for Graduates in Medicine

JOHN A. KOLMER, M.D.

Professor of Pathology in the Philadelphia Polyclinic and College for Graduates in Medicine

PHILADELPHIA

During the past two years we have had, through the generosity of a benefactor, the opportunity of prosecuting an inquiry into the cause and nature of psoriasis with the purpose of better enabling us to treat this prevalent and obstinate disease of the skin. This work has been carried out in specially equipped laboratories and with all possible thoroughness. Psoriasis

is a disease that has been known since the days of the early Greeks, who characterized it by the name of "lepra." Despite the fact that it constitutes from 4 to 5 per cent. of all skin-diseases, the nature of the disease has remained thus far an enigma. Many theories have been advanced to explain its pathogenicity, but none has been satisfactorily demonstrated to be true. The three most prevailing views with regard to psoriasis are that (1) psoriasis is due to a parasite, (2) psoriasis is a disease resulting from disturbed metabolism, and (3) psoriasis is a disease of neuropathic origin. The last view referred to, while advocated by some men of prominence, has relatively little to commend it.

We have concentrated our activities in investigating psoriasis along two particular lines of inquiry—bacteriologic and metabolic. We have labored assiduously during the period of our investigation to find some micro-organism in the scales, serum, skin and blood of patients suffering from psoriasis, but we have thus far been unable to discover any micro-organism which could be regarded as bearing an etiologic relationship to the disease. Twenty-two different microbes have been isolated by us from psoriasis scales and have been individually studied with a view of determining their special characteristics. Complement-fixation tests have been carried out with groups of these organisms with entirely negative results. We have likewise made up vaccines with the isolated bacteria, but have failed to produce any effect on psoriasis by their use. The ultramicroscope and all sorts of special culture mediums have been employed without materially aiding us in elucidating the cause of psoriasis. We have not abandoned the bacteriologic study of psoriasis, but up to the present time it may be said that no germ has been found which could be regarded as bearing a causative relation to the disease.

-METABOLIC INVESTIGATIONS

During the past two years we have investigated the metabolism of about a dozen patients suffering from psoriasis. Obviously, that which first commanded our attention was the protein metabolism. We have carried out investigations of the nitrogen balance in patients for long periods of time under the most rigid conditions. The food received by patients was analyzed and weighed, and the nitrogen in the urine and feces was carefully determined. The scales were collected with as much care as possible and their nitrogen content likewise determined. In one instance the perspiration was collected for certain periods of time and subjected to analysis. The patients were housed in private rooms and were under the care of a special trained nurse. Our patients were studied for periods varying between forty and 168 days.

In all our studies of the protein metabolism, attention was paid to possible qualitative disturbances as well as quantitative. The distribution of the urinary nitrogen was therefore studied in most of the cases. Our patients were kept on diets containing definite quantities of nitrogen and a definite caloric value. The total nitrogen intake was compared with the total nitrogen output and balances established.

Our work was not very far advanced when we began to realize that we were dealing with a disease the subjects of which suffered from a peculiar disturbance in protein metabolism. We learned very soon that these patients possessed the power of retaining rather large quantities of nitrogen on diets on which

* Read before the Section on Dermatology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

normal persons would just maintain equilibrium. The giving of a diet containing large quantities of nitrogen (about 20 gm. a day) was followed by an enormous retention of nitrogen. And what is perhaps more important, on a very low-nitrogen diet, that is, a diet containing about 4 gm. of nitrogen a day, on which a normal person can hardly maintain equilibrium or at best do so with great difficulty, the psoriatic patient has the power of so altering his protein catabolism as to maintain equilibrium with perfect ease. The psoriatic patient possesses the power of reducing the urinary nitrogen output to a level lower than has ever been recorded in the studies of protein metabolism.

Clinically, we noted a very definite relationship between the protein metabolism and the course of the eruption. In the active stages of the disease, a high-protein diet brings about a spread of the eruption; conversely, a low-protein diet is followed by improvement even when no local remedies are applied.

Two questions presented themselves as soon as these facts were recognized:

- 1. What is the nature of the relationship between the protein metabolism and the psoriatic processes of the skin?
- 2. What is the cause of the nitrogen retention observed in psoriatic patients?

We believe that answers to these questions may be found in the consideration of the following:

One of the most prominent features of the psoriatic lesion is the rapid proliferation of the epithelial cells. These cells become cornified and are thrown off as scales. Repeated analysis has demonstrated that these scales are composed almost entirely of pure protein; in severe forms of psoriasis very large quantities of scales may be exfoliated, entailing the loss of considerable amounts of protein material. The epithelial cells for their life and growth require large quantities of building material in the form of protein, which can come from only one source, the blood and lymph.

It is a well-established fact that the growth and multiplication of cells depends directly on their "growth impulse" or *Wachstumstrieb*, and that the velocity of their growth can be regulated entirely by the amount and character of "building material" placed at the disposal of these cells.

It becomes evident, therefore, that any diet which will tend to increase the concentration of amino-acids in the blood and lymph will tend to accelerate the growth and multiplication of these rapidly growing cells. A high-protein diet strongly favors the spread of the psoriatic lesions, because it causes an increase in the concentration in the blood of the various building materials, and places at the disposal of the psoriatic cells a plentiful supply of nutrient material.

A low diet, on the other hand, appears to influence the psoriatic lesion in just the opposite way. The concentration of amino-acids does not rise above the normal, and what is perhaps more important, the protein catabolism is reduced to the lowest level possible.

No harm whatsoever is caused by keeping a patient on a very low-protein diet for a long period of time, provided the caloric supply is sufficient to maintain the patient's body-weight. Chittenden for a number of years has advocated the advisability of keeping man on a 6-gm. level of nitrogen, and Hindelhede has shown that nitrogen equilibrium and mental and physical efficiency can be maintained for long periods of time on diets containing even less nitrogen.

In the accompanying table are given different type diets which we have employed in the treatment of our psoriatic patients. They contain from 4 to 5 gm. of nitrogen and sufficient calories to cover the needs of a man doing a moderate amount of work. In hard-working persons additional butter and cream can be added. Our patients were allowed plenty of sugar, and in some cases candy was given between meals.

TYPE OF REGIMEN FOUND TO BE MOST BENEFICIAL IN PSORIASIS

These two diets give an idea of the way dietaries of this nature can be arranged, without losing sight of the necessity of a certain amount of variety in the menu. Oysters and ice-cream may be added to the diet, as they contain very little nitrogen. During the spring and summer when berries and fresh vegetables are plentiful, these diets can be made more varied.

For patients who are up and about attending to their business, it would be advisable to have them submit their twenty-four-hour specimen of urine about once a week for analysis. The urine, if the patient adhered rigidly to the dietary prescription, should not contain more than from 3.5 to 4 gm. of nitrogen. If it contains more it is safe to assume that the patient is not

living on the prescribed diet. Early recognition of this fact will be of service to both the patient and the physician.

There are many dermatologists who state that they have tried dietary restriction in psoriasis, but have failed to observe the beneficial results claimed for this method of treatment. It should here be stated that the more severe and wide-spread the eruption the more readily will it be influenced by appropriate diet, and on the contrary, the more limited the eruption the more difficult will it be to influence it by diet alone. We have tested the influence of diet under most critical conditions and we feel fully justified in stating that the eruption of psoriasis may be favorably or unfavorably influenced by variations in dietary regimen. We have not failed in a single instance to bring about marked improvement in our research patients by diet alone. We are free to admit that outside of the hospital our results have been much inferior to those obtained with hospital patients, for the latter are supplied with the exact kind of food in measured quantities.

It is necessary, to secure the best results, that the diet should not contain more than 5 gm. of nitrogen a day. Very few private patients who are not given detailed instructions as to the quantity of the various foodstuffs to be taken will reach so low a level. Such a low-protein dietary may be difficult for those with epicurean tastes to content themselves on; our patients, however, lived on a regimen of this character for many weeks without complaint.

We have no doubt that many patients with severe and obstinate psoriasis eruptions would be willing to adhere to such a diet to secure a disappearance of their eruption. How long it is necessary or desirable for a psoriatic patient to continue this rigid diet we are not quite prepared to say. We have found that several weeks of this regimen will usually alter the reactivity of the skin to external medicaments, so that an eruption which is too inflammatory to permit of the use of chrysarobin or other strong applications in the beginning, afterward will yield readily to such local treatment.

One of our patients who had a universal psoriasis has remained practically free for a year by adherence to a diet similar to that on which she subsisted in the hospital. The more nearly the diet approximates the type of diets referred to above, the more quiescent will the psoriatic process remain.

It may, however, be undesirable by reason of the condition of the patient's nutrition and general health to continue on such a diet too long. We have reason to believe that a low-nitrogen intake may favorably influence other wide-spread dermatoses. We have cured a rebellious case of exfoliative dermatitis of two years' duration and have seen striking improvement in a case of chronic generalized eczema and in a case of dermatitis herpetiformis while under this treatment, the two latter patients using no local treatment to speak of.

In psoriasis, dermatitis exfoliativa and allied conditions in which there is a great multiplication and a casting off of the epithelial cells, the low-protein diet seems to quiet down the condition by a process of epithelial cell starvation. Sweet, Corson-White and Saxon have shown that inoculation-tumors of mice and rats may be similarly influenced by a very low-protein diet.

THE GERMICIDAL PROPERTIES OF CHRYSAROBIN AND CERTAIN OTHER REMEDIES

In 1877 an Englishman, Keith, first employed chrysarobin in the treatment of psoriasis. The drug had been previously used by Balmanno Squire of London, in the treatment of ringworm of the scalp. Chrysarobin is a remarkable substance which exerts a powerfully beneficial and rapid influence on the patches of psoriasis. No other drug can be compared with chrysarobin in its rapidity of effect. In many cases it acts almost as a local specific. The drug is derived from the woody fiber of the *Andira araroba* tree, the crude product being known as Goa powder. From almost time immemorial the natives of Brazil have employed this powder in the treatment of skin-diseases.

It was thought profitable to investigate the germicidal activity of chrysarobin and certain other medicaments employed in psoriasis with a view of shedding collateral light on the nature of the disease. It is obvious that if chrysarobin proved to be powerfully

Fig. 1.—Extensive psoriasis eruption.

germicidal, this fact would aid in interpreting its effect on psoriasis patches. If, on the other hand, chrysarobin possessed only feeble or no germicidal power, such facts would likewise be helpful in offering a solution of its mode of action. In our investigations difficulty was experienced at the outset in determining the germicidal power of chrysarobin because this drug is insoluble in water. The Rideal-Walker and the Hygienic Laboratory methods of determining the germicidal power of drugs apply only to substances which are soluble. We were therefore obliged to devise a method of determining the germ-killing power of insoluble substances. By a stroke of good fortune, we selected calomel as a standard. We have already published¹ a note on the germicidal activity of calomel. We found that calomel, as well as other mercurials, possessed, *in vitro*, the most powerful germ-destroying influence of any known drugs. Weight for weight,

1. Schamberg, J. F., and Kolmer, J. A.: The Germicidal Activity of Calomel, *THE JOURNAL A. M. A.*, June 20, 1914, p. 1950.

calomel was found to be just as germicidal as mercuric chlorid. This is all the more remarkable when one considers the insolubility of the former. Having determined that insoluble substances were capable of destroying bacterial life in solid mediums in the Petri dish, we were enabled to test out the activity of chrysarobin and certain allied substances. Chrysarobin in the highest amount used (120 mg. or 2 grains in 10 c.c. of bouillon) failed to restrain bacterial growth. We have furthermore incorporated chrysarobin in various culture-mediums in such excess that the powdered drug floated on the surface of the medium and yet staphylococci and the ringworm fungus were capable of producing a flourishing growth on such mediums. We have supplemented this study by various other investigations, all of which confirm the fact that chrysarobin possesses but feeble or no germicidal action.

We do not feel as yet justified in drawing any definite deductions from these facts, but merely desire to

Fig. 2.—Same patient ten weeks later, showing improvement in eruption as a result of low-protein diet. No internal treatment and no external applications whatsoever.

state our findings. Chrysarobin, the most powerful and efficacious drug known in psoriasis, has practically no germicidal power. Calomel, on the other hand, which we have found to be highly germicidal and capable of destroying the cocci in the skin, has but a feeble effect on the patches of psoriasis.

THE BIOCHEMICAL ACTION AND CHEMOTHERAPEUTIC STUDIES OF CHRYSAROBIN AND ALLIED SUBSTANCES

We have endeavored to determine the changes which take place in the skin when chrysarobin and certain allied products are applied. It is a well-known fact that chrysarobin produces a curious mahogany-colored discoloration of the skin which lasts until an exfoliation of the stained horny cells takes place. It would appear that the greater the degree of staining, the more beneficial is the effect of the drug on the disease. We have shown by a series of experiments,

which will be detailed at full length elsewhere, that chrysarobin has a powerful affinity for certain elements of protein. Indeed, the staining of the scales by chrysarobin produces a firmer union than the staining of the scales by any known anilin dyes. The staining of the skin appears to be intimately associated with the process of oxidation. Chrysarobin is powerfully reducing, and in undergoing oxidation, abstracts oxygen from the protein of cells, for we have demonstrated that the oxidation can go in the absence of air in a hydrogen atmosphere. We believe from our experiments that the effect of chrysarobin is in large part due to two influences: (1) the firm union with the protein of the epithelial cells and (2) the abstraction of oxygen. It is quite possible that this may explain the favorable influence of the drug in psoriasis, for the action referred to may restrain the great proliferative activity of the epidermal cells which characterizes this disease.

Some investigators, chief among whom was Unna, maintained some years ago that chrysarobin produced its favorable influence in psoriasis by abstraction of oxygen, the drug being oxidized into chrysophanic acid, a reddish-brown substance. The investigations which we have carried out seem to support the view that the reducing power of chrysarobin is of great importance in influencing its therapeutic efficacy. As has been stated, this action and the remarkable chemical affinity of chrysarobin for protein, particularly for the keratins of the skin, appear to us to be in large part responsible for the beneficial influence of this drug. Psoriasis scales which are incubated with a watery suspension of chrysarobin at 37 C. (98.6 F.) are deeply stained by the drug. The chemical combination is so firm that it is impossible to remove its coloration even by prolonged boiling with glacial acetic acid. The chemical combination of chrysarobin with protein is apparently stronger than that of any known anilin dye.

Recent investigations into the chemical constitution of chrysarobin have revealed the fact that it consists of a number of chemically allied substances. Following the work of certain other chemists, we have isolated the two important ingredients of chrysarobin, chrysophanol-anthranol and emodinol. We have tried out these substances clinically and have found that emodinol exerts no therapeutic effect whatsoever, while chrysophanol-anthranol has a favorable influence, but inferior to that of crude chrysarobin. We then tried to isolate by fractional extraction the therapeutically active parts of chrysarobin; the fractions, however, were always inferior to the whole drug. Compounds of chrysarobin in which the hydroxyl group was combined with the acetyl radical, acetylchrysarobins, were prepared by us and tested out therapeutically. We found these compounds likewise inferior to chrysarobin. A number of other compounds prepared by us in which the hydroxyl groups of chrysarobin were partially or completely oxidized were therapeutically of little or no value; in general, it can be stated that any change in the chrysarobin molecule affecting the hydroxyl groups diminishes the therapeutic activity on the skin. We have produced a certain derivative of chrysarobin in which the hydroxyl groups appear to remain unaltered which has greatly interested us. This new drug has been tried out by ourselves and other dermatologists to whom it has been supplied, and the general feeling is that it is superior to chrysarobin. It is also preferable to chrys-

arobin in that it is much cleaner and freer of disagreeable staining properties. The mode of standardizing the preparation of this drug has not been satisfactorily concluded by us, and we shall therefore delay publication on this matter until a later date.

ABSTRACT OF DISCUSSION

DR. WILLIAM A. PUSEY, Chicago: I confess to the same skepticism concerning the value of a low protein diet in psoriasis that has been shown previously in discussing this subject. I am unable to reconcile the remarkable accumulation of nitrogen in these patients with the law of the indestructibility of matter, nor am I convinced that in eliminating from the diet protein we have solved the problem of the treatment of psoriasis. I admit that a reduction of the protein intake as well as in the quantity of food in general is a factor in the improvement that has been observed in these cases; and I also believe that the decrease in protein is more important than the decrease in the general diet; but a long and unhappy experience with psoriatic patients, who have been dieted most vigorously with food of a low protein content, has convinced me that in the diet we have but one factor in the etiology of this affection of the skin.

DR. G. W. RAIZISS, Philadelphia: As chrysarobin has long been known to give good results in psoriasis, it was interesting for us to learn more about the nature of the chemical processes which are involved in the action of the drug on the skin. Unna maintains that the favorable action of chrysarobin on the skin in this affection is due to the abstraction of oxygen from the cells of the skin, but this theory was never supported by experimental work. Our own experiments rather support the view of Unna that the reducing power of chrysarobin has something to do with its favorable influence on psoriatic lesions, but we found another important property in the drug, namely, that it had a remarkable chemical affinity for protein, especially the keratin elements of the skin. We applied a chrysarobin ointment to the skin of a rabbit, and after several days, when this section of skin was excised, it was found to be deeply stained with a chrysophanic acid-like color, and we could not separate the acid from the skin by any method which we employed. We also found that this staining could be accomplished by mere suspension of the drug in water, and again we could not remove the stain from the skin. This shows that chrysarobin has probably a remarkable chemical affinity for proteins, and that it apparently acts by precipitating the cell and robbing it of its vital properties by absorbing important proteins. Recent studies of chrysarobin show that it is not a single definite chemical compound; it consists of a number of chemically allied substances, and it was our aim to isolate some of these with the object of finding a principle which would be superior to the commercial drug. While none of the constituents of chrysarobin appeared to be of greater therapeutic value than the entire drug, one of many derivatives of chrysarobin, which were prepared by us and tested on the skin, gave good results. This substance is still the object of chemical and clinical studies.

DR. JOHN A. KOLMER, Philadelphia: Those of you who have done any work along these lines are aware of the fact that many varieties of cocci and diplococci are found in these lesions. We have not been able to identify any one of these as the active agent in psoriasis. The difficulties surrounding the work are increased because psoriasis is apparently not transmissible to the lower animals. Our results along these lines have thus far been negative. During the past year we have been mainly interested in studying the action of chrysarobin on psoriatic lesions and determining whether the drug had a germicidal action on any of these micro-organisms. We have been able to grow cocci from psoriatic lesions in chrysarobin, showing that it has a very weak if any germicidal influence. This fact has been corroborated by control experiments. Calomel is absolutely insoluble in water, yet we found that this drug has a remarkable

germicidal activity, equal to mercuric chlorid, and capable of killing organisms directly on the skin. This drug, however, has no recognized value in the treatment of psoriasis, and we have become convinced that chrysarobin does not act by any direct germicidal action on micro-organisms in psoriatic patches. It is probably by gradual deoxidation that chrysarobin destroys a micro-organism in psoriatic patches; what that particular micro-parasite is, is something yet to be discovered.

DR. WILLIAM S. GOTTHEIL, New York: How far was Dr. Schamberg able to carry his protein-free diet, and how long could he keep it up? Personally and in private practice I have found that the limit was soon reached; two weeks has been the longest that I have ever been able to keep a patient on it, and not with a very strictly protein-free diet at that.

DR. S. POLLITZER, New York: My own experience with a relatively low protein diet in psoriasis has not been so fortunate as that of Dr. Schamberg. Within the past year I have tried it in ten cases in private practice, all intelligent patients on whose word I could rely, who were kept on a diet as nearly free from nitrogen as it was possible to enforce, though, of course, they were not under hospital supervision. I am satisfied that they faithfully followed the prescribed diet, which excluded even peas and beans. None of these patients showed anything like the improvement reported by Dr. Schamberg: in fact, three of them developed new lesions in the third week of this diet. My own experience has been duplicated by many others, though that of Dr. Schamberg is by no means unique, and it is rather curious that such radically different results should have been obtained by different observers. I can only repeat my conviction, that there is some error in these findings. To take the most striking case: A girl of 40 kilos (88 pounds) "retained" 400 gm. of nitrogen during the four months of the experiment and actually weighed a little less at the end of the period than when she began. In other words, about 25 pounds of protein which this patient ingested has disappeared; it has not passed out again and, as her weight proves, it has not remained in her. I must insist that such a result is not only a contradiction of the laws of metabolism, but even a violation of the fundamental principle of the indestructibility of matter. The case which Dr. Schamberg presents as an answer to Tidey's criticism, that the authors' error lay in a failure properly to collect scales, proves too much. This psoriatic, who did not desquamate, also "retained" nitrogen. Now, the authors have explained the nitrogen "retention" as due to a specific nitrogen-hunger caused by the loss of protein in the scales. But here is a case that does not scale, cannot therefore have a specific nitrogen-hunger and yet "retains" nitrogen! A large positive nitrogen balance over a prolonged period without a corresponding gain in weight is in itself a proof of error in the observations.

DR. JAY F. SCHAMBERG, Philadelphia: Replying to Dr. Pollitzer, lack of time forbids me to enter into detail to prove that the figures presented present no inconsistency. Passing to another criticism, physiologic chemists are agreed as to what constitutes a nitrogen retention, and we have employed the term in the manner in which it is universally used by chemists. The chemists associated with me in our research are convinced that the results we have reported are not only possible but also correct. One who is a dermatologist and not a chemist is not warranted in branding the results as impossible and out of accord with physiologic chemical principles. In presenting these results, we have no theory to suggest or prove. We entered into this investigation with entirely open minds. I was at the outset skeptical as to the influence of diet in psoriasis, but I have been convinced practically against my will. Psoriasis may ultimately be proved to be a disease of purely parasitic origin. We are not advancing hypotheses as to the cause of the disease: we are presenting our laboratory and clinical findings and we place them before you for what they are worth, and for your careful consideration.

WHITE-SPOT DISEASE*

GEORGE M. MACKEE, M.D.

AND

FRED WISE, M.D.

NEW YORK

The designation "white-spot," as applied to a definite clinical entity referable to the skin, was first employed by Westberg in 1901. He used the term "white-spot" merely as a descriptive adjective, qualifying a supposedly unknown dermatosis. In 1903, Johnston and Sherwell published the second paper on the subject, giving it the title of "White-Spot Disease." In this paper reference was made to Westberg's case and to Montgomery's case of white-spot disease which was exhibited before the American Dermatological Association in 1901, a report of which case was later published in full. Sherwell subsequently exhibited another case of this disease before the New York Dermatological Society in 1904. By that time a number of dermatoses, characterized by the presence of white spots of one kind or another, were reported in the dermatologic literature of America and Europe.

During the past ten years a very substantial literary structure has reared itself on the foundations of Westberg's and Johnston and Sherwell's papers. A careful and thorough perusal of the writings on the subject

Fig. 1.—The two lesions on the penis. Note the annular appearance, due to the snow-white border and the mother-of-pearl or bluish-white center. Note, also, the crenated border.

of white-spot disease has given us the impression that the cases deserving to be placed in the same category with those of Westberg, and Johnston and Sherwell are by no means numerous. Highly instructive and interesting contributions to the subject have been rendered by some of the master minds of dermatology both here and abroad. Of these dissertations, however, valuable as they are, only a few actually deal with the subject of so-called white-spot disease.

As is the case with so many other unclassified dermatoses in which the etiology is purely conjectural, the clinical picture not clearly defined and even the microscopic changes more or less obscure and difficult of interpretation, the study of white-spot disease has led investigators far afield in their attempts to place it into its fitting nosologic position with relation to allied cutaneous changes. Thus, in the excellent contributions of Vignolo-Lutati, Riecke, Hazen, Petges and others, we find that these authors evidently considered it necessary, for a thorough presentation of the subject, to digress considerably from the main

theme. For they deal not only with white-spot disease *per se*, but also with morphea guttata and scleroderma circumscriptum, as well as the card-like scleroderma of Unna, the lichen albus of von Zumbusch, the lichen planus atrophicus and sclerosus of Hallopeau, the dermatitis lichenoides chronica atrophicans of Csillag, the neurodermatitis alba of Kreibich, the nevus anemicus of Voerner, the multiple keloids with scar-like atrophies of Jadassohn, the white, atrophic and scar-like perifollicular spots on the trunk of Iwanow, the morphea with maculae atrophicæ of Duhring, the circumscribed scleroderma of Zarubin, the white spots found in various chronic diseases such as leprosy, dermatitis herpetiformis and a number of other morbid cutaneous processes of more or less remote relationship to white-spot disease.

We have read and studied the entire literature relating to white-spot disease and have found it necessary to write an article of sixty-five typewritten

Fig. 2.—White spots occurring in dermatitis herpetiformis. Such lesions are found in pediculosis corporis, acne vulgaris, lepra, etc. They have nothing in common with the lesions of white-spot disease.

pages in order to give credit to the various authors, and properly to express and support our contentions. In the fifteen minutes at our disposal it is, of course, impossible to do more than to give the essential clinical and histologic details of the cases under our personal observation and to give the conclusions we arrived at after a careful study of the question. If at this time we do not seem to be fair to other investigators and if we do not appear to prove our contentions, we ask our colleagues to await the publication of the entire article before criticizing our findings.

Evidently, a judicious scheme of elimination would seem desirable in order to clarify the subject, at least so far as our present-day knowledge will permit. In order to avoid confusion it would appear to be a good plan to omit the polemic discussion of the cutaneous changes which obviously have but little if any bearing

* Read before the Section on Dermatology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

* From the Dermatological Department of the College of Physicians and Surgeons, Columbia University.

on the subject of white-spot disease or morphea guttata or circumscribed scleroderma, in any of their varied clinical and pathologic manifestations. Interesting as these remotely related disease-processes undoubtedly are, it can hardly be said that their inclusion in a discussion dealing with white-spot disease is in any way conducive to a clear understanding of an already involved subject.

We shall at once exclude all but three groups of cases. These three groups consist of the unclassified group, consisting mainly of the cases of Westberg, Johnston and Sherwell, Hazen and Riecke; the sclero-

Fig. 3.—Acanthosis over center of lesion (from microphotograph, first biopsy, low power). Under this is a triangular-shaped area of cellular infiltration with its apex at lower part of reticular layer. At base of triangle is a large area of degeneration. This area contains a crystalline deposit (artefact) which shows in the picture.

derma group and the lichen planus sclerosus group. Following the lead of Montgomery and Ormsby, Petges and others, we believe that lichen planus sclerosus, which is the same disease as lichen albus, while having clinical and pathologic features resembling, to a certain extent, localized scleroderma, can be clearly differentiated. We, therefore, exclude the lichen planus group. This leaves for consideration the four or five unidentified cases and the cases that have been clearly shown to belong to scleroderma.

We will state here that we believe the term "white-spot disease" should be retained, but limited to cases that can be grouped with scleroderma, accepting Unna's card-like scleroderma as the type.

In other words, our conception of scleroderma is a broad one and in a way may be likened to that of syphilis, in which there are a number of different cutaneous eruptions. In this way we would have white-spot disease represent a distinct type of scleroderma just as morphea is a distinct type of scleroderma.

CHARACTERISTICS OF THE DISEASE

The clinical findings in the reported cases have varied to a considerable degree, but we believe that this is merely an expression of the various stages of evolution. We present herewith a composite clinical picture of the affection.

White-spot disease occurs mostly in females, especially in those of a neurotic temperament. It may occur in childhood and in early and late adult life. Most of the reported cases were in the third and fourth decade. The disease is essentially chronic in its course, the lesions making their appearance insidiously and developing slowly. Aside from moderate pruritus at the beginning, subjective symptoms are rare. The sites of predilection are at the base of the

neck, in front and behind, the upper portion of the chest and back, but the lesions may appear on the extremities, various portions of the trunk, on the genitals, etc.

The essential lesion is a small white spot. The color may be snow white, ivory white, bluish-white, etc. The lesions may vary in size from a pin-head to a dime. They may be isolated, sparse and widely scattered, or they may be numerous, grouped and confluent. The surface may be smooth or wrinkled, glistening or dull, depressed or slightly elevated or level with the surrounding skin. There may be slight telangiectasia. The center of the lesion may appear depressed. There may be a violaceous areola. They may contain horny plugs and they may be scaly.

To the palpating finger the lesions may be imperceptible, or they may impart a sense of resistance.

It is far more difficult to give a composite picture of the histopathology because most of the cases differ, especially with regard to details. In the majority of instances there was a thickening of the horny layer. In a few cases there were dilated follicles filled with keratin. The granular layer and the rete were thinned, the basal layer irregular and the interpapillary prolongations lost. There were usually a number of spaces directly under the epidermis which were probably dilated lymph-vessels. This fact is rather interesting because Unna considers these spaces partly responsible for the white color.

The chief changes in the derma consist, in the early stages, of a more or less circumscribed area of perivascular round-cell infiltration, edema and other signs of inflammation. Later, there is a marked increase of connective tissue, the infiltrate, except at the periphery, disappears and the blood-vessels and lymph-spaces diminish in number and size. Elastic tissue is usually lost or greatly diminished. In other words the general picture is that of scleroderma.

Fig. 4.—Epidermis sinuous (from microphotograph, second biopsy six months later, low power). Loss of interpapillary prolongations. Disappearance of cellular infiltrations. Hypertrophy of collagen.

REPORT OF CASE

Before going any further we desire to place on record a case of white-spot disease that was observed in Dr. Fordyce's clinic.

Patient.—Man, aged 43. The eruption had existed for four months. The patient stated that he noticed the four lesions at the same time and that they had not changed in appearance since he first noticed them. We were unable to decide whether the lesions had developed slowly or suddenly. There were no subjective symptoms. Syphilis and tuberculosis were excluded.

Examination (November, 1913).—The patient is a tall, thin man of distinctly neurotic type. A general physical examination revealed nothing of interest. The entire cutaneous surface, including the visible mucous membranes, was normal, with the exception of the lesions about to be described. There was absolutely no sign of lichen planus. The eruption consisted of four lesions, two of which were on the dorsal

Fig. 5.—Tissue removed from a lesion which closely resembled white-spot disease. The histologic picture is that of lichen planus. Note the extensive subepidermal vacuolization.

surface of the penis and two on the anterior surface of the scrotum. They were all about the same size, roughly speaking, about 0.5 mm. in diameter. The lower penile lesion was a little larger than the others. There was a marked disk-like configuration, with a well-defined, slightly irregular or crenated border. The penile lesions appeared as though they were embedded in the skin, like mosaic; this appearance was less marked in the scrotal lesions. Palpation revealed slightly perceptible infiltration, but there was no distinct sense of resistance. The margin was, perhaps, very slightly elevated, while the center was apparently depressed and from a clinical point of view seemed to be slightly atrophic. The color was the most striking feature. The border of each lesion was an opaque, glistening white, resembling porcelain. The center was semitranslucent and bluish white, resembling mother-of-pearl. The upper penile lesion was surrounded by a slight violaceous band. The surface of the lesions was smooth.

The patient was not seen again until the latter part of May, 1914, after an interval of six months. There was no change in the clinical appearance of the lesions.

Histopathology.—Both of the penile lesions were excised in their entirety for the purpose of histopathologic study. The upper lesion was removed in November, 1913, and the lower one in May, 1914.

First Biopsy: The central part of the lesion shows a general hypertrophy of the epidermis with a central depression or dell. The interpapillary pegs have united to form a broad plate. The horny and granular layers are thicker here than in any other portion of the section. The rete is also increased in thickness; the cells stain poorly and the prickles are indistinct; a number of the cells have lost their nuclei. The basal layer is irregular, vacuolated and is not sharply differentiated from the underlying cutis.

Derma: In the center of the lesion the derma is occupied by a somewhat triangular-shaped area of small round-cell infiltration with the base of the triangle close to the epidermis,

and its apex situated in the lowermost portion of the reticular layer. This infiltration consists for the most part of lymphocytes, with plasma-cells and fibroblasts scattered throughout the area. Where the infiltration is most dense, collagen is practically absent. There has been an increase in the number of capillaries but most of the vessels have been occluded by endothelial proliferation and by the compression exerted by the cellular infiltration. Just under the epidermis and extending the full width of the diseased area, is a zone of colliquative degeneration or necrosis. Here the tissue elements are no longer discernible. In a few sections a large subepidermic cavity was noted in the degenerated area. This was occupied by a homogeneous mass containing a few cells and reminded us of a similar condition found in Johnston and Sherwell's case.

At the margin of the lesion the interpapillary pegs are flattened out. The papillary layer shows a condensation with subepidermic spaces. Here there are a few scattered lymphocytes, plasma-cells and chromatophores. In the reticular layer the collagenous bundles are composed of very coarse fibers, separated here and there by edema. There are a few circumscribed areas of round-cell infiltration closely limited to degenerated and occluded vessels. The only appendages noted were a few coil-glands which appeared to be dilated and were surrounded by a moderate round-cell infiltration.

Second Biopsy: The epidermic changes consist of an entire flattening out of the interpapillary pegs. The horny and granular layers and the rete appear normal.

Derma: There is a distinct fibrosis, hyperplasia, in the upper two-thirds of the cutis. The tissue is dense and stains deeply with eosin. Here we find large, coarse, wavy fibers. In the upper corium the blood-vessels are reduced in number and size; the endothelium is prominent. There are a few areas of moderate perivascular round-cell infiltration. In the rest of the corium the only cells found are fibroblasts. In the lower third of the cutis the collagenous tissue consists of a fine network of delicate fibers producing the appearance of areolar tissue. Elastic tissue is present directly

Fig. 6.—Tissue removed from a lesion conforming clinically to white-spot disease. The atrophy of the epidermis, loss of rete pegs, sclerosis of papillary layer and upper reticular layer together with underlying zone of infiltration, points to lichen planus sclerosus. Illustration taken from Fordyce's article on lichen planus (*Jour. Cutan. Dis.*).

under the epidermis. Then there is a narrow zone extending through the lesion where the elastic tissue is either absent or badly fragmented. Lower down it again appears and, with the exception of some fragmentation, is practically normal.

Summary.—The disease apparently began as an inflammation with a perivascular infiltration of small round cells. These areas then united to form a diffuse infiltration in the center of the lesion. The inflammation was apparently intense enough to produce degenerative changes in the upper part of the corium. The epidermic changes were probably secondary.

Sections made from tissue obtained six months later show a disappearance of the inflammation with hypertrophy of collagen, loss of vessels, elastic tissue and rete pegs.

We also studied three cases of lichen planus sclerosus, representing three different stages of evolution, but these cases will not be reported here.

It will be recalled that we accept, as examples of white-spot disease, twenty cases that have been definitely identified as scleroderma and that we excluded lichen planus sclerosus and many other conditions.

This leaves for discussion the unclassified cases reported by Westberg, Johnston and Sherwell, Hazen

combines the unclassified cases of white-spot disease with the cases falling under the general heading of scleroderma.

CONCLUSIONS

White-spot disease is a special form or type of scleroderma which can be differentiated, both clinically and histologically, from other affections with white lesions.

Lichen planus sclerosus and atrophicus or lichen albus, although giving rise to white lesions, has nothing in common with white-spot disease.

The unclassified cases of white-spot disease, such as those of Westberg, Johnston and Sherwell and Hazen, belong to the scleroderma group and, therefore, are true examples of white-spot disease.

The discrepancies in histologic and clinical findings are due to the fact that the studies were made at different times with respect to the evolution of the disease.

We desire to thank Dr. John A. Fordyce for his kindness in placing at our disposal the material that forms the basis of this study. We wish to express our gratitude to the staff of the Dermatological Laboratory for the careful technical work. We especially desire to thank Dr. Elizabeth C. Jagle for her aid in the study and interpretation of difficult material.

ABSTRACT OF DISCUSSION

DR. H. H. HAZEN, Washington, D. C.: Drs. MacKee and Wise were most fortunate in being able to perform biopsies at such varying intervals, and to demonstrate that a process originally showing rarefaction of the corium may eventually terminate in morphea. It would seem that they have solved the question of the various unclassified cases, my own among the number, of white-spot disease, and that these cases are true scleroderma. While I have lost sight of my patient I know where she is living and shall try to obtain more tissue from her in the hopes of confirming the observations of Drs. MacKee and Wise.

DR. F. W. CREGOR, Indianapolis: I direct attention to the similarity between the histopathologic picture presented by Dr. MacKee in this case and that given by Dr. M. B. Hartzell in connection with his paper on granuloma annulare. I previously made the statement that I had not heretofore considered granuloma annulare an entity, and now, in comparing these two histopathologic pictures, I must confess that if each were an entity I would have great difficulty in differentiating one from the other microscopically.

Fig. 7.—Tissue removed from a lesion in a case of lichen planus presenting lesions simulating white-spot disease. Atrophy of epidermis. Rete pegs almost obliterated. Sclerosis of papillary layer. Hypertrophy of collagen of reticular layer. Blood-vessels markedly reduced in number. No infiltration.

and Riecke. Unfortunately, time will not allow of a discussion of the details of these cases so that we can only give our conclusions concerning them. Our early lesion showed the loss of collagen reported by Johnston and Sherwell and by Hazen. Montgomery and Ormsby and Unna also noted loss of collagen in early lesions. Our late lesion depicted the hypertrophy of collagen and other changes observed by most investigators. If we had been compelled to rely entirely on the histologic findings in our early lesion our case would have been classed in the group containing Johnston and Sherwell's and Hazen's cases. On the other hand, if we had only the later lesion to study, the case would have been added to the scleroderma group. We assume, therefore, that if these investigators had been able to study their cases at different stages of evolution, an entirely different conclusion would have been reached. We believe that our case

RADIUM

ITS USE AND LIMITATIONS IN SKIN-DISEASES *

FRANK E. SIMPSON, M.D.

CHICAGO

The scope of this paper is limited to the use of radium in dermatology.

In radium therapy everything depends on the proper equipment and the technic.

For dermatologic cases I have used varnish applicators of different types.

A useful style of apparatus is the so-called "toile" or flexible linen applicator. One apparatus of this type is rectangular in shape, covers 12 sq. cm. of surface and is of one-twentieth strength.

Other applicators have metal instead of linen backs, are square or round and are of one-fourth, one-half or full strength. As the applicators are constructed so

* Read before the Section on Dermatology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

that 10 mg. of the radium salt are spread over 1 sq. cm. of surface, a one-twentieth-strength applicator contains about 0.5 mg.; a one-fourth-strength, 2.5 mg.;

nomenclature that will express the amount of radium element instead of radium salt in each square centimeter of the applicator, a terminology that has much in its favor.

The chief advantage of the varnish applicators over other styles of apparatus lies in the uniformity of their

Fig. 1.—Epithelioma of left temple; photograph taken May, 1913.

Fig. 2.—Patient in Figure 1, after eight hours' treatment with $\frac{1}{4}$ -strength radium applicator screened with 0.1 mm. silver; photograph taken July, 1913; no recurrence to present time.

action over their entire surface. Certain types of radium applicators produce a more intense reaction at the point of application than at the periphery of a lesion, which is an obvious disadvantage.

The technic of radium treatment is extremely varied

Fig. 3.—Epithelioma of right side of face; photograph taken July, 1913.

Fig. 4.—Patient in Figure 3, after ten hours' treatment with $\frac{1}{4}$ -strength radium applicator screened with 0.1 mm. silver; photograph taken October, 1913; no recurrence to present time.

and can be learned only by a certain amount of experience with each applicator.

In general, one uses the apparatus either naked, that is, wrapped only in rubber tissue, or with screens of metal interposed between the applicator and the

a one-half-strength, 5 mg., and a full strength, 10 mg. of radium sulphate to each square centimeter of applied surface. Many authors prefer the use of a

skin. Lead, silver, aluminum, brass and platinum have been largely used as screens, but a tendency is now noted toward the discontinuance of lead screens on account of the irritating secondary rays developed when the radium rays pass through lead. I have commonly used screens of aluminum or silver which are

too far advanced to be materially benefited. It would be premature to try to draw conclusions at present as to the relative efficiency of radium and the Roentgen ray in epithelioma. Both agents, I believe, have distinct fields of usefulness in this disease.

Epithelioma may be healed with radium, applied

Fig. 5.—Lupus erythematosus of nine years' duration, symmetrically involving nose and both cheeks; photograph taken February, 1913.

Fig. 6.—Patient in Figure 5 after treatment with $\frac{1}{4}$ - and $\frac{1}{2}$ -strength radium applicators unscreened; photograph taken April, 1914.

covered with from five to ten thicknesses of black paper to absorb the secondary rays, the whole apparatus being then enveloped in rubber tissue and applied to the skin by adhesive or rubber bands.

Radium reactions in the skin have sometimes been compared too closely with Roentgen-ray reactions. In general, radium reactions are much more benign than Roentgen-ray reactions, and when destructive inflammation has been produced, healing is much less slow and uncertain. This is especially true of the reactions in which beta-rays predominate, but even severe gamma-ray reactions are more benign than severe Roentgen-ray reactions.

In order to limit my remarks, only three groups of diseases will be touched on at this time: epithelioma, lupus erythematosus and angioma.

EPITHELIOMA

It has been sufficiently demonstrated that radium is a very efficient agent in epithelioma of the skin. Up to the present time I have treated about forty cases. To a certain extent these were selected cases, being of the type usually treated by the dermatologist. In two of these cases success was only partial; but healing, I believe, might have been brought about had I been able to continue the treatment. The general experience, however, leads to the belief that certain epitheliomas are probably resistant to radium as well as to other forms of actinotherapy, while other cases are

without or with a screen. Without a screen, an epithelioma 2 or 3 cm. in diameter and not too deeply situated may be healed with a one-fourth-strength applicator in five or six treatments of an hour each. With a screen of 0.1 mm. of silver, eight hours may be required. Recently I have made more frequent use of screens in order to limit the inflammatory

Fig. 7.—Lupus erythematosus of eight years' duration involving right cheek and upper lip; photograph taken February, 1913.

Fig. 8.—Patient in Figure 7 after treatment with $\frac{1}{4}$ - and $\frac{1}{2}$ -strength radium applicator unscreened; photograph taken July, 1914.

reaction and because experience has shown that the deeper parts of the growth are probably better reached. An epithelioma can also be healed with a single massive dose of heavily screened radium, but I have hitherto preferred to use fractional doses. The method

of operation is determined solely by the nature of the growth and the convenience of administering the treatments. The cosmetic results are equal if not superior to those obtained by any other method.

relieved symptomatically. Under radium treatment a few inoperable cancers in various situations have been made operable and a few have apparently recovered.

LUPUS ERYTHEMATOSUS

About twenty cases have been treated. In view of the intractable nature of this disease, the results of radium treatment are on the whole very encouraging. In selected cases I have been able to obtain complete involution of the disease. Unfortunately, relapses may occur; but these so far have yielded to persistent treatment. The painless character of the applications enables one to pursue the treatment vigorously. The technic has much to do with success or failure. The chronic "fixed" types are best treated with destructive doses. Experience with this disease has led me recently to prefer screened radium. I now use in the

Fig. 9.—Cavernous vascular nevus of upper lip; photograph taken April, 1914.

Fig. 10.—Patient in Figure 9 after treatment by "cross-firing" with $\frac{1}{4}$ - and $\frac{1}{2}$ -strength radium applicators screened with 0.1 and 0.5 mm. silver; ten exposures of fifteen minutes each; nevus was removed without visible inflammatory reaction; treatment not quite completed; photograph taken May, 1914.

While the treatment of internal cancer with radium is not germane to the present discussion, a few remarks may be made on this important topic. In general the present attitude of most workers with radium in cancer of the deeper structures is one of strict conservatism. Few writers go so far as Bumm,¹ who believes that in the future cancer will be treated by radiotherapy. Most authors agree with Wickham and Degrais,² who in a recent article take the position that radium is to be regarded strictly as an adjunct to surgery.

The general opinion seems to be that operable cancers should be operated on. Radium may be of great value prior or subsequent to operation. Inoperable cancers may be treated with radium to minimize suffering and perhaps prolong life. Inoperable cancer in some situations, as in the cervix uteri, may be wonderfully

Fig. 11.—Vascular purplish-red nevus, irregularly elevated and deeply infiltrated; photograph taken September, 1913.

Fig. 12.—Patient in Figure 11 after treatment with $\frac{1}{4}$ - and $\frac{1}{2}$ -strength radium applicators unscreened; nevus was removed with three series of exposures of about four hours each; the small patch at corner of mouth has not been treated; photographed May, 1914.

average case a one-fourth- or one-half-strength applicator screened with 0.1 mm. of silver, and treat each patch from about four to six hours in the course of two weeks. The inflammatory reaction is thus ren-

1. Bumm, E.: Further Results with Radium Therapy in Carcinoma, Berl. klin. Wehnschr., 1914, li, 193.
2. Wickham and Degrais: Can Radium Be of Value to Surgery in the Treatment of Malignant Tumors? Fortschr. a. d. Geb. d. Roentgenstrahl., 1913, xxi, 333.

dered less severe than when naked radium is used. Unfortunately, some patients, when they first come under observation, are more or less scarred by the disease or by previous treatment. Even in these cases the cosmetic result is sometimes quite satisfactory. In selected cases of not too long duration or of too large area a very good cosmetic result has been obtained.

ANGIOMA

The results obtained in certain types of nevus vascularis (birth-marks) are superior to those hitherto obtained by any other method. In a certain number of angiomas radium offers the only practical method of treatment. It is particularly successful in the angiomas of children on account of its painlessness.

Large flat angiomas (port wine stains) of deep red color can often be treated with a good cosmetic result. While amenable to several different technics, "port wine stains" are most successfully treated by giving just enough raying to produce a marked erythema with desquamation. With a one-twentieth-strength applicator screened with 0.01 mm. of aluminum the proper amount of reaction can be produced in about four or five hours. Several repetitions of this treatment will often result in a satisfactory decolorization.

Elevated, papillomatous angiomas must be treated with slightly stronger doses in order to level the surface and bring about decolorization. With a one-fourth-strength applicator, unscreened, an exposure of from two to four hours may be given in fractional doses. When the reaction subsides, the series of treatments may be repeated if necessary. Several courses of such treatment will usually bring about the desired result.

With certain types of cavernous angiomas in children, a reduction and leveling of the tumor can sometimes be produced without visible inflammatory reaction. This shows the specific and selective action of radium on the blood-vessels. In these cases I have used either a one-half- or one-fourth-strength applicator screened with 0.1 mm. of silver, and have given exposures of fifteen or twenty minutes' duration.

To attain the best results in angiomas, infinite care and attention to detail are needed. While the cosmetic results are naturally not always absolutely perfect, the enormous improvement is so noteworthy as to be nearly always satisfactory to patients. In selected cases an almost perfect cosmetic result can be obtained.

59 East Madison Street.

THE RELATIVE VALUE OF RADIUM IN DERMATOLOGY*

ARTHUR F. HOLDING, M.D.

NEW YORK

On account of the extravagant exploitations of radium by the profession as well as by laymen, a statement as to its actual value as a therapeutic agent (at present) may be enlightening. The majority of physicians are not in a position to judge the merits of this element, because its scarcity and high price place it beyond their reach. Judging from the unusual publicity accorded the discovery of this new chemical, with its marvelous physical properties, it was logical to

expect that the therapeutic results would be quite phenomenal; but such results take years to perfect. The premature, hothouse exploitation of radium, hybridized by a cross between its unusual phenomena and the publicity given them, have resulted in disappointment, which was to be expected. After the initial period of exploitation, every new therapeutic agent goes through an evolutionary period in the hands of those who are scientifically inquisitive, and eventually its true value is established. For instance, the Roentgen rays, which were discovered seven years before the discovery of radium, are now just beginning to be employed scientifically, and it will be some years hence before the prejudice and skepticism resulting from premature, unscientific and extravagant exploitation of the Roentgen rays can be dispelled. In the same way the preposterous claims of radium fanatics provoke one to an underestimation of its value.

For two purposes one must acknowledge that radium has greater possibilities than any other similar agent in use at present, namely, (1) in diseases of faulty metabolism, in which the radium emanatorium may be used, and (2) in malignant lesions of cavities, in which the neoplasm is inaccessible or difficult to expose to direct application of Roentgen rays, such as the esophagus, rectum, vagina, urinary bladder, fauces, etc.

The application of radium to benign growths is unnecessary in my opinion, because benign conditions can be controlled more quickly and easily and with less expense by the electric desiccation method of Clark, and by massive doses of Roentgen rays.

One fact that would seem to justify hopes of superior results from radium is that the most penetrating Roentgen rays in use represent the output of a 60,000 to 100,000 volt current, while it is estimated that an electric current of from 600,000 to 1,000,000 volts would be necessary in order to produce Roentgen rays of as great penetration as the most penetrating rays of radium, that is, currents ten times greater than the strongest currents now employed for the Roentgen rays. Previous to the advent of improved Roentgen-ray tubes of the Coolidge type this argument was more convincing than at present; with the penetration of the Roentgen rays completely under one's control, it is reasonable to hope that Roentgen rays can soon be generated, having nearly as high a penetration as the gamma rays of radium, and it is certain that Roentgen rays can be produced from electrical sources in greater quantity and at less expense than the gamma rays of radium can be obtained.

The field of usefulness of radium has been greatly increased since the employment of radium emanations. The bulk of radium is so small that formerly it could be applied only to limited areas. The present method is to draw off the emanations of radium into glass capillary tubes, which retain for about twenty-four hours a radio-activity approximately equal to that of the original radium. A lesion of any size can be covered by these glass tubes, arranged parallel to each other. By the addition of fresh emanation each day to these mats of parallel tubes the radio-activity can be continued indefinitely. In the field of local applications to lesions of the skin and mucous membrane the agents to be compared with radium are electrical desiccation (Clark), ultraviolet rays (as applicable from a Kromayer lamp), massive doses of Roentgen rays of controllable penetration (Coolidge), surgery and destruction by caustics, cautery or cold. In com-

* Read before the Section on Dermatology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

paring the relative value of these methods eight points should be considered.

1. Cost: Radium is far more expensive than any of the other methods. Massive Roentgen rays, electric desiccation and ultraviolet rays come next in expense. Surgery and caustics are the cheapest.

2. Ease of Application: As to ease of application, much depends on the training of the person who administers the treatment. Each therapist will naturally do the best work with the greatest ease by employing that agent with which he is most familiar. Other things being equal, radium and caustics are easier to apply than the other agents in question.

3. Time Consumed in Treatment: Radium applications are much longer in duration than any of the other methods. They require hours while the other treatments require minutes.

4. Pain: Radium, Roentgen-ray and ultraviolet light treatments in proper dosage cause no pain. Electric desiccation and carbon dioxid snow cause slight pain. Surgery and cauterization are very painful and require a local anesthetic. Chemical caustics are the most painful.

5. Cosmetic Effects: Cosmetic effects are best after radium, Roentgen rays, ultraviolet light, desiccation and carbon dioxid snow, and poorest after surgery or cautery.

6. Dangers: With a proper technic there are no dangers in any of these methods. Poor technic is a *de facto* contraindication for the use of any agent.

7. Superficial Healing and Deep Extension: The well-demonstrated superficial healing powers of radium and the Roentgen rays should not mislead one into attempting to cure too extensive a lesion with these agents alone, lest the lesion make deep inroads while valuable time is wasted on superficial healing.

8. Indications in Dermatology: Non-malignant and skin conditions, such as warts, moles, nevi, acquired blemishes like tattoo marks or keloids, lupus, ureteral caruncles, mycosis fungoides, blastomycosis and acnes can most readily be controlled by electric desiccation (Clark). If one has the equipment, massive doses of Roentgen rays, carbon dioxid snow and ultraviolet rays may be used in these conditions with advantage. Radium will give good results, provided the radium and time necessary are available. For superficial lesions surgery is contra-indicated, because better cosmetic results can be obtained with less danger and less pain by non-surgical methods. Psoriasis, eczemas and skin-diseases due to faulty metabolism should be treated first by systemic measures, including radium emanation, if available. When this does not produce the desired results, electrical methods such as massive Roentgen rays are indicated. In deeper malignant conditions of the skin, the following therapeutic program should be adopted:

1. Massive Roentgen deep therapy or massive radium deep therapy.

2. Complete radical operation, preferably by bloodless methods such as thermopenetration, electrocautery, or massive caustics (Stroebe).

3. Effulguration (de Keating-Hart) into the wound.

4. Postoperative Roentgen deep therapy or massive radium deep therapy.

In hopeless malignant skin conditions the patient's symptoms can frequently be much ameliorated by massive deep roentgenotherapy or radiotherapy.

103 Park Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SIMPSON AND HOLDING

DR. WILLIAM DUANE, Boston: Radium is continually producing radio-active gas, and when the gas comes in contact with any material substance, that substance in turn becomes radio-active. In a small glass tube, containing the gas, I placed a thin sheet of steel and it also has become radio-active, as can be easily demonstrated by breaking the tube, removing the steel and holding it near a phosphorescent salt. Some years ago I suggested that sheets of metal or other substances, made radio-active in this way, should be used instead of the radium itself in the treatment of cancers. This method has certain advantages over the use of radium itself. It is very flexible. The applicators may be of any size and shape desired, and may have any strength. They will lose their activity after a certain time, and are then of no further value until again exposed to the radium emanations. A number of cases have been treated by the staff of the Harvard Cancer Commission at the Huntington Hospital by this method of deposited activity. The most complete removals of malignant tumors we have observed so far, were treated in this way. Dr. Simpson is correct in his statement concerning the differences between the Roentgen rays and the radium rays. Physical scientists tell us that four kinds of rays come from radium, the alpha-, beta-, gamma- and delta-rays. It is known that the gamma-rays are similar but not exactly the same as the Roentgen rays. During the past two years much important work has been done on these rays, and we have learned that Roentgen rays are very short waves of ultraviolet light. Gamma-rays are still shorter. The alpha- and beta-rays are of a totally different nature. They are corpuscular and not regular waves. We also get two kinds of rays from the Roentgen-ray tube; one depends on the tension of the tube and the other on the antikathode. In answer to Dr. Dyer as to how long a piece of metal will remain active after being exposed to these radium emanations, the activity will last on an average of a little over an hour, gradually dropping to zero. The dosage can be accurately measured, as it always follows the same law. A tube of this kind filled with radium emanation will lose one-half its strength in four days; in four more days it will again be one-half weaker, and so on, losing one-half its strength every four days.

DR. ISADORE DYER, New Orleans: What method does Dr. Duane employ in obtaining these radium emanations? Is it necessary to use a glass tube? How long does the steel or other substance used remain radio-active?

DR. HENRY C. BAUM, Syracuse: How long can the metal remain in the unopened tube before losing its activity?

DR. FRED WISE, New York: What factors are necessary to produce a lesser or a stronger activity?

DR. JAY F. SCHAMBERG, Philadelphia: I have had some experience with radium during the past seven years, but have not had a sufficient quantity to produce the effects that Dr. Simpson has achieved, and with the amount at my disposal I have not grown wildly enthusiastic concerning its effects on cancers of the skin, in which I have seen equally good results obtained with the Roentgen ray. Radium has one distinct advantage over the Roentgen ray—the constancy of the dosage. With radium one knows the exact amount of energy that is given forth; we secure a constant effect from a certain quantity in a certain time from a certain distance. Despite the various energy-measuring devices that have been used to secure precision of dosage of the Roentgen ray, there is still latitude for error. Radium also has the advantage of simplicity of application and of applicability to certain cavities of the body which are inaccessible to the Roentgen rays. Another advantage is the kindliness with which radium burns heal. I had an experience with this on my own skin, on which an experimental radium burn, although deep enough to produce necrosis, healed promptly without pain, leaving only a slightly depressed scar. A Roentgen-ray burn of the same depth would have caused more trouble.

DR. WILLIAM A. PUSEY, Chicago: I have used radium in a glass capsule for many years, and in an applicator for the past year or two, and in spite of all the care and judgment I could exercise, I have been unable to distinguish any difference whatsoever between radium and Roentgen-ray reactions. The radium burns with which I am familiar are produced by an abundance of the beta-rays as well as the gamma-rays, and they are identical with the burns produced by the soft Roentgen-ray tube. They produce the same kind of vesication with a necrotic pellicle, and, contrary to Dr. Schamberg's experience, heal with the same relative benignness. I see no difference whatever in clinical effects, between radium and the Roentgen ray. My standard of radium work has been Wickham's book—confined largely, I must confess, to a study of the pictures—and I can duplicate from my work with the Roentgen ray any of the results of the radium treatment shown in Wickham's book, including his results in the treatment of vascular nevi. The results of the radium and the Roentgen rays are due to the effect of actinic energy on the skin, and the actinic properties of both are identical as far as we can judge by all physical criteria. We are at present going through such a brain storm about radium as we went through with the Roentgen ray about ten years ago. We have gone into ecstasies about radium in cancer but the fact should be clearly fixed in our minds that in radium we are using a form of radiant energy similar to what we have been using for the past ten or fifteen years in malignant and pseudo-malignant growths throughout the body. We are destroying these cells wherever they are accessible but not where they are not accessible, and therefore we are not curing with radium lesions that are beyond the reach of radiant energy. We have not cured malignant growths in the cavities of the body with Roentgen rays; it is not now being done with the new "deep methods" with Roentgen rays or with radium, and the claims which are being made now for radium—as well as for the German "tiefen therapie" with Roentgen rays, are, in view of what we already know, unscientific and unreliable.

DR. GEORGE M. MACKEE, New York: I regard the action of radium and the Roentgen ray as practically identical, and I doubt if there is any lesion, not excepting nevi, that can be affected by radium that cannot be equally well treated with the Roentgen ray. While radium can be more easily applied to lesions in cavities, especially the mouth, yet, unfortunately, here the new growths are so malignant that I doubt whether radium is of much value in their treatment, except occasionally. I was much surprised to hear Dr. Schamberg say that the dosage of radium could be so much more readily gauged than that of the Roentgen ray. My view is exactly the opposite. The dose of the Roentgen ray can be gauged with almost absolute accuracy, as for instance in ringworm of the scalp, for which accurate dosage is absolutely essential. One disadvantage of the radium application, as compared to that of the Roentgen ray, is that the former must sometimes be continued for from four to twelve hours to get exactly the same result that could be obtained by one application of the Roentgen ray lasting from one to fifteen minutes. Dr. Duane's point concerning the deposited activity of radium was interesting. We have an analogous form of treatment with different kinds of metals that have been acted on by the Roentgen rays. The difference is that, heretofore, low vacuum tubes have been used, which gave out a different form of radiant energy from that of the gamma-rays. As to radiodermatitis produced by the filtered or the unfiltered rays, there is no difference between them except in degree, depending on the dosage.

DR. RICHARD L. SUTTON, Kansas City, Mo.: I disagree with Dr. Schamberg concerning the character of radium burns. Recently I had under my care a case of cancer *en cuirasse* which had been treated with radium. While the patient was little if at all benefited she was severely burned at a dozen or more points where the agent had been applied. The lesions healed slowly, and were very painful. Despite treatment, several of the burns were still present when the patient died, four months after her return from the sanatorium.

DR. FRANK E. SIMPSON, Chicago: I believe there is no question among physicists that the Roentgen rays and radium rays have certain differences: that the latter contain certain rays that have no analogue in the Roentgen rays. I do not agree at all with Drs. Pusey and MacKee that they both produce the same reaction or result on the skin. The fact that they are all forms of radiant energy does not imply that they are identical. I think there are certain things that can be done with radium that cannot be or at least have not been duplicated with the Roentgen ray. I have seen many cases of angioma successfully treated with radium that could not be duplicated with the Roentgen ray. As to lupus erythematosus, especially in lesions about the nose or eyes, I do not think such patients can be well treated with the Roentgen rays, lest we set up a severe reaction, while with radium I do not hesitate. In this disease radium is really worth while. Certain types of epithelioma I believe can be treated just as well with the Roentgen ray as with radium but there are other cases that do not yield to Roentgen rays. One of my friends, one of the best roentgenologists in Chicago, brought me a case which had absolutely failed to yield to the Roentgen rays, and it yielded very promptly to radium. This is a common experience with others who have used both agents. This may be partially a matter of technic. The form of induced radio-activity described by Dr. Duane, I think would prove very valuable in certain types of epithelioma, but it would be of less value in other dermatologic conditions, such as angioma, the treatment of which requires a certain amount of skilful cosmetic work.

RADIUM AND THE ROENTGEN RAYS IN RADIOTHERAPY

THEIR USES AND LIMITATIONS *

WILLIAM S. NEWCOMET, M.D.

PHILADELPHIA

Rays generated from a Crookes tube may be considered as being identical with those eliminated from radium, varying somewhat, however, in regard to force; therefore before consideration of their therapeutic value, a comparison between them in regard to a few of the more important points dependent on their physical nature might be of interest, it being assumed that the general properties of these elements and the ordinary Roentgen apparatus are too well known to be rehearsed in this article.

The cathode- and the beta-ray seem to be analogous; the two have the same properties except in regard to speed. While the cathode-ray travels 5,000 miles a second, either from or impinging on the surface of the anode, causing the formation of Roentgen rays, the beta-ray is disrupted or exploded from the atom of one of these radio-active salts and leaves it at a rate of from 45,000 to 100,000 miles a second, generating during this disturbance the gamma-ray.

It is obvious that when we have a force of 5,000 miles a second on one side with another of from 45,000 to 100,000 on the other, the result must necessarily differ. A comparison of this with a large number of bullets being projected from or impinging on a surface, in one instance the force being from nine to twenty times greater than the other, gives us an analogy. It follows, as might be expected, that the gamma-ray has far greater penetrating powers than any Roentgen ray so far known, and while it may be possible to build a Roentgen tube that will give the required speed

* Read before the Section on Pharmacology and Therapeutics at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

to the cathode particle, as yet, with our present knowledge of physics, it has not been produced and there is no likelihood of its being accomplished.

Physiologically, the difference between low and high radiation is of the greatest importance; while the low rays are always most active, they lack penetration, and it is well known that the so-called burn is likely to follow their indiscriminate use. Therefore, on account of their activity and lack of penetration they are not so desirable as the higher rays, which possess penetration and are by no means so active in producing tissue change. This point may seem somewhat contradictory, but on analysis it will be found that experience and theory support each other. Let it be taken for granted that as these active low rays pass through tissue, a cell, here and there, feels the full force of the radiation while others are protected. This gives rise to a process in which may be found conditions varying from stimulation on the one hand to necrosis on the other; whereas, under the influence of

ried a fairly large proportion of high beta-rays, which, although thought to be useless, have from an experimental point of view a pronounced physiologic significance, and it may be possible that as these gamma-rays are projected through the tissues, the formation of secondary beta-rays may cause the more active change in tissues so commonly seen in reactions from radium.

This may, however, be due to another condition, which is possibly secondary but plays a distinct rôle in the issue between Roentgen and natural radiation; when the former is employed, the point of origin of the rays is usually from 10 to 20 inches from the body, and in this bundle of rays is a wide variation of one variety, a high tube containing a predominance of high rays, while in a low tube the opposite condition prevails. This, however, suffers modification between limits.

From radium spring three distinct forms of radiation: the first may be discarded, as it lacks penetration and would prove useful only when the naked salt was employed; unfortunately, by its exclusion, about 90 per cent. of energy is lost. The gamma radiation, which is supposed to be the important form, from a medical point of view, equals only about 1 per cent. There is not, however, the least doubt that when the medium beta-rays are employed it is possible to obtain about 7 per cent. efficiency of the whole mass, although it is on this point that there exists the greatest conflict of opinion concerning the two forms of radiation. The difference between radium, thorium and actinium in regard to the proportion of the different rays depends largely on the elements that go to make up the individual group; but it must be conceded that the gamma-ray of thorium possesses greater penetration than that of the other two groups. Necessarily this is also true of the beta- and alpha-ray. While some authorities assert that this is a distinct advantage, sufficient proof has not been given for its adoption as absolute.

The mode of application of these radio-active elements differs from that of the Roentgen rays; for instance, the radio-active salt is usually applied to the affected part in close proximity to the disease; therefore, we have a given amount of high-penetrating rays springing from a point near to, and not at a distance, as is usual in Roentgen radiation. This point is of more material interest if several sittings are given, for should there be any tissue between the diseased portion and the radio-active salt, it is not likely to receive the activity at more than one sitting.

Therefore, from a physical point of view, the following differences are observed between Roentgen radiation and the radiation from these elements:

First, the rays differ in penetration.

Second, it is possible the high beta-rays also play a very active rôle, and consequently differ in quality.

Third, the relation of the radiation to the surface and the several planes of tissue is materially altered.

Another point which has been brought out in Bayet's publication is that the dosage of these radio-active elements can be measured with an exactness that is absolutely impossible in Roentgen radiation, and while this is true to a great extent, the variation in the amount of radiation from a Crookes tube is not of sufficient importance to cause it to be made an issue; furthermore, the idiosyncrasies that exist to both forms of radiation cause more anxiety and are more important than the slight variation in dosage.

From the physical difference which has just been cited as existing between these two forms of radiation

Fig. 1.—Diagram: A, showing the relation of radiation to the surface and the penetration of equal proportions; compare with C, filter surrounding the radio-active elements and a frequent change of base possible. B and D, comparative curves showing penetration of the different rays.

the high radiation, the effects are more uniform, each cell receiving an equal amount of radiation. If this be true macroscopically, then why not apply the same microscopically? For instance, the important part of the cell is its nucleus, and therefore, if the radiation is obstructed by the cell elements, the nucleus, being protected by them, naturally escapes; this causes an inflammatory reaction, but it is doubtful if it results in the death of the cell. On the other hand, if the radiation is high, all parts of the cell receive about the same amount of radiation and this causes an equal amount of degeneration in all parts and consequent death of the nucleus. Therefore, on this theory the high rays should prove most desirable as a therapeutic agent.

A second difference between the Roentgen radiation and that of these radio-active elements is that there is not the least doubt that with the gamma-ray is car-

tion, it would be expected that the effect on tissue would also be materially altered; and this view is further substantiated by observation. It might be said that the reaction produced by these radio-active salts is decidedly more intense, is usually confined to a limited area and is in turn followed by a fairly rapid restoration of the part; the same degree of reaction produced by the Roentgen ray would be more widespread, the damage to the tissue in the affected part

Fig. 2.—Epithelioma of the buccal surface of the mouth; extensive involvement, perforating the cheek at the site of the present dimple. Result obtained from 11 mg. specimen radium (records of the American Oncologic Hospital). (A similar case relieved by applications of 1 mg. Referred by Dr. J. B. Deaver.)

more uniform, and healing extremely slow. Even the reaction of a chronic character caused by these radio-active elements, as observed in the laboratory worker, will rapidly disappear if the process has not been allowed to progress too far, while the same amount of damage done by the Roentgen ray would produce results that would possibly last a lifetime.

It can be easily seen that under these conditions it is possible to use the radio-active elements and do less harm to surrounding structures than by the other form of radiation, and attention has been called to the fact that very few poor results have been seen from radium. This is thought by some authorities to be due to the care taken in making these applications; possibly this assertion may be correct, for the warning was given by its predecessor, and very few care to witness the burns which were contracted in the early days of the Roentgen ray. Too much credit, however, must not be given to those applying radium, for those differences of a physical nature which exist and seem to be material in this issue cannot be overlooked.

Curiously, however, the varying susceptibility to these radio-active elements seems to be in greater proportion than to the Roentgen radiation. Many observers have called attention to the severe reaction that is frequently seen; it is most alarming when it occurs, and is very likely to cause considerable anxiety; in the person of good physique it is not likely to result seriously, but in the weak and debilitated it may lead to serious consequences; the intense, rapid inflammation may lead to an extensive cellulitis, with its train of concurring symptoms, and usually follows the course natural to that condition, quite in contrast to the inflammatory reaction that follows the application of the Roentgen ray. On the other hand, cases are often seen in which it appears to be quite impossible

to produce the expected reaction, and the tolerance almost borders on an immunity.

Therefore the difference between the reaction caused by these two forms of radiation may be stated as follows:

1. Exact dosage is possible with these radio-active elements.
2. The personal idiosyncrasies are far greater.
3. The reaction is more localized and more intense.
4. Resolution occurs earlier.
5. There is less damage done to surrounding tissues.
6. That Roentgen burns have been treated and healed by radium is sufficient to prove its wide variation.

While the difference between these two forms of radiation is being compared, attention must be called to those reports in medical literature in which these radio-active elements have been employed successfully in the treatment of cases after the Roentgen rays had failed; yet at the same time a few have been reported under the reversed conditions. These reports, however, have usually been made by those interested in one form of radiation alone, and therefore must be considered accordingly; but to substantiate the idea that there is a difference in effect on the tissue elements there is a third series of cases reported by those who have employed both forms of radiation for some of these troublesome cases. It would seem that it should and would be far better to employ the two forms of radiation, thereby obtaining the desired reaction from each. Under certain conditions the ease of application to the surface necessarily elects the employment of one of these radio-active elements; as such may be cited when cancer exists in cavities, as, for instance, in the mouth, rectum or vagina.

In cancer of the uterus, radium seems to possess a control that is not observed from any other form of treatment, and while it is rarely permanent it gives

Fig. 3.—E. S. Epithelioma of palate perforating the nasal cavities. Notice the damage. Healed by applications of 4 mg. radium element. (From records of American Oncologic Hospital.) Referred by Dr. H. R. Wharton.

comfort to the patient and materially alters the course of the disease.

These elements can be applied in cavities in which it is impossible to bring the radiation from the Roentgen tube without penetrating the intervening tissue, and it is in this field that the results from these elements seem to be somewhat better than those from the Roentgen ray. Such conditions as polypi within the larynx can be treated without the injury that

leaves the imprint of previous treatment on the overlying skin. In some instances carcinoma of the palate and others of the buccal mucous membrane have been healed. It must not be understood, however, that these radio-active elements are a panacea for cancer; they are far from it; but individual results are often seen that are most gratifying and excite our enthusiasm, though this is not the rule. Here, again, many by their interest in these radio-active elements have in

Fig. 4.—Rodent ulcer of ala of nose; ulceration; was treated during the spring of 1909 by 1 mg. of radium element and remained healed until 1913 when it was again healed by applications from a specimen containing 11 mg. radium element. (From records of American Oncologic Hospital.) Referred by Dr. A. Hewson.

their haste forgotten to look back on the number of patients "cured" by the Roentgen rays. (The word "cured" can certainly be used in its fullest meaning; objection, however, should be made to its employment as a general rule.)

To prove these instances it might be well to recall a few cases that have come under observation and treatment.

CASE 1 (Case of Dr. H. R. Wharton's).—A man, aged about 60, who suffered from an inoperable carcinoma of the cecum, was treated with the Roentgen rays. Four years have elapsed with no recurrence and he is still in good health.

CASE 2 (Case referred by Dr. Chandler).—A woman, aged about 40, suffering from an inoperable carcinoma of the pylorus, irregular in shape and about the size of two fists, was treated. Seven years have elapsed and she is still in good health.

CASE 3.—A patient with recurrent carcinoma of the breast, referred by Dr. McClary, treated seven years ago, is still in good health.

CASE 4 (Reported by Dr. Shoemaker).—A woman, with an inoperable sarcoma of the pelvis, with extensive involvement, and about the size of a seven months' pregnant uterus, was treated about ten years ago; the whole mass disappeared and pregnancy resulted twice afterward; when last heard from she was living in the West and was in good health.

Certainly the superficial epithelioma is in most instances promptly relieved by both forms of radiation, but here radium has so many rivals that its only recommendation is the popularity of its cost. The cosmetic results are exceptionally good, and possibly in those cases in which the Roentgen rays have failed, radium often promotes the desired result. In many reports the term "rodent ulcer" is used to signify all small epitheliomas occurring on the face; this is unfortunate, as the usual form is the proliferative fungoid type, which is far from being so malignant.

The true rodent ulcer with its undercut edges, which has penetrated below the superficial tissues, is rarely cured by any form of treatment. Epitheliomas or recurrent epitheliomas appearing on scar tissue of low vitality are also as a rule unfavorable cases for either form of radiation.

In deep cancer the choice between massive doses of deep radiation and the employment of these radio-active elements must be considered an open question. Its employment in new growths as sarcoma and fibroma is a matter of individual opinion, and results have been reported from advocates of both; the only possible advantage of these radio-active elements is the ease of manipulation. But it should be remembered that the failure of one form of radiation is no criterion of the other.

There is one field, however, in which these radio-active elements displace the Roentgen rays: that is, in the treatment of nevi, either the simple port-wine stain and the deeply pigmented mole, or those with slight vascularity to those of the deep cavernous variety. While these lesions have been treated by the Roentgen rays, the method is extremely dangerous and the results are usually poor. On account of the vascularity, the character of the burns sometimes produced will cause ulcerations that last for years, and when healed give rise to scars with more or less telangiectasis that are as a rule more unsightly than the preexisting nevus.

The amount and quality of the radiation from these radio-active elements are, at present, still an issue to be decided, although some authors have given support to the prevailing idea that beneficial results depend largely on the amount of radio-active element. This, however, is not the fact, and several instances have come under observation in which very small amounts of radium, used merely as a placebo, completely healed one epithelioma perforating the palate between the

Fig. 5.—Sarcoma of orbit, recurrent, treated by 11 mg. radium element. Growth caused a bulging of the temple about the size of a small split apple. Referred by Dr. Swenck. (Records of American Oncologic Hospital.)

nasal and buccal cavity, and another between the buccal cavity and the cheek. The first case was referred by Dr. H. R. Wharton and the second by Dr. J. B. Deaver. They were both inoperable. These results are frequently seen in all fields of radiology, and one should never despair until the individual case has been given the benefit of the doubt.

The comparison of dosage between these two forms of radiation is an impossibility; the existing difference

in their physical nature, their physiologic action and the mode of application does not permit it. The wide difference of opinion existing between individuals using the same form of radiation makes it difficult to analyze the results, which in all events depend largely on the manner and skill of employment rather than the quality and quantity of apparatus. Therefore at present dosage in all fields of radiation is a variable quantity that must depend entirely on the opinion of the operator.

From this short analysis of the two forms of radiation we may conclude that:

1. Both forms of radiation have wide ranges of usefulness that differ materially under certain conditions of disease, individual idiosyncrasy and adaptability of usefulness to the affected part.

2. There is, however, a wide middle ground in which the two forms of radiation overlap, their employment being a matter of convenience.

3. The use of both forms of radiation will in some instances yield results, when one alone would fail.

Therefore, those employing these radio-active elements should have a knowledge of Roentgen radiation. Experience is also necessary with either form to obtain results, and, furthermore, to guard against untoward effects that are so commonly seen.

3501 Baring Street.

THE PLACE OF THE ROENTGEN RAY IN THERAPEUTICS *

GEORGE C. JOHNSTON, M.D.

PITTSBURGH

The purpose of this paper is to present in abstract form certain information concerning Roentgen therapy with the essentials of which physicians in general should be quite familiar. That this is not the case, however, is proved by the questions so frequently propounded to the roentgenologist by his professional brethren, which questions display frequently a profound ignorance both of what may be obtained in the way of results by this method of treatment and the reason why such results may be expected to follow treatment. The deleterious effects of radiation on tissue (thanks to the unfortunate series of accidents occurring in the early history of the use of this agent for diagnostic purposes) are perfectly familiar to the profession; in fact, it was the occurrence of so-called Roentgen-ray burns following exposure for diagnostic purposes that first suggested that an agent capable of such destructive influences on healthy tissue might be possessed of considerable power as an alternative agent on pathologic tissue.

Beginning with the use of the ray as a depilatory and as a stimulant in the hands of the dermatologist in chronic acne, eczema, etc., experience soon taught that profound effects could be produced on superficial lesions. This was followed by experiments in the treatment of goiter, lymphatic leukemia and tuberculous glands as well as the superficial forms of malignancy, until within the last few years a new field has been opened by the employment of heavy doses with decided filtration in the treatment of gynecologic lesions deep in the pelvis.

It is thus seen that a wide range of activity has been shown to be possessed by this agent, and it is small wonder that many physicians are unable to understand how a radiation can so profoundly influence such widely different structures in such varied situations. Therefore a word of explanation of some elementary principles of Roentgen therapy: The Roentgen-ray manifests its physiologic action only on those tissues in which it is absorbed. The most striking illustration of this is shown by Pfahler, who in treating a sarcoma of the neck with deeply penetrating rays produced a dermatitis on the opposite side of the neck. It is therefore necessary in attempting to effect tissue changes of a beneficial character in pathologic tissue to employ tubes capable of emitting a radiation having sufficient penetration to reach down to the lowest portions of the affected tissue. In general, this is accomplished by a variation in the vacuum of the tube, the high-vacuum tube emitting high radiation, the low-vacuum radiations of slight penetration. By means of the unique tube invented by Dr. Coolidge, it is possible to handle the tube and apparatus so as to cause emission of large quantities of radiation having a uniform and predetermined penetration; but with all the usual forms of Roentgen tube, a variety of radiations are emitted not in uniform proportion to each other. A high-vacuum tube, for example, will emit rays of high penetration and in addition a variable quantity of rays of much lower penetration depending on the age of the tube and the amount of seasoning to which it has been subjected.

It is possible to handle a tube so as to produce a peculiar condition of stability of vacuum, constituting what is known as a seasoned tube, in which the proportion of rays of high penetration will be quite great and the proportion of rays of lesser penetration emitted relatively small.

It is further possible by interposing filters of leather or aluminum between the tube and the tissue under treatment, to intercept practically all the soft slightly penetrating rays, thus subjecting the tissue to a bombardment of rays consisting almost entirely of those of a predetermined and desired penetration.

The deeper the lesion to be attacked lies beneath the surface, the greater the penetration of the rays necessary to affect it, while the more superficial the lesion, the less the penetration of rays desired. This is highly important, as for example in the treatment of a patch of lupus situated on the forehead, if the operator should use tubes of high penetration, he would probably succeed in producing some results on the lupus due to the rays of lesser penetration emitted by the tube, but prolonged treatment would be necessary, since the majority of rays emitted would pass completely through the lesion and be intercepted in the bone of the skull and the end-result would be a periostitis, necrosis and exfoliation of the bone underlying the lesion. I have seen this produced in several cases in which the enthusiasm of the physician possessed of a piece of new apparatus was greater than his experience in its use.

In the treatment of superficial lesions, tubes of very low penetration without the intervention of filters are required. A few applications of the radiation from such tubes is sufficient to provoke in the skin a violent reaction, which is followed frequently by the disappearance of the lesion and its replacement by healthy scar tissue. Under such circumstances, a large

* Read before the Section on Pharmacology and Therapeutics at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

majority of the radiation emitted from the tube is absorbed in the tissue involved by the disease, and the action of this radiation when it is absorbed on diseased tissue is a profound one. This is not the time or place to produce a voluminous condensation of the literature on this subject, interesting as it might be to discuss the histologic changes manifested in tissue that has been exposed; but the whole thing can be summed up in a few words which are sufficiently accurate for our purpose and which may explain why such a treatment is followed by results either good or bad.

Normal human tissues in health are possessed of a certain degree of vitality. They react to various stimuli, electrical, chemical or mechanical, in a uniform degree. Healthy tissue possesses a certain degree of physiologic resistance to irritating or destructive stimuli. It is also possessed of certain well-marked reparative powers when injured.

Diseased tissue, on the contrary, is in an entirely different condition. If malignancy, for example, be present, the tissue is composed of rapidly growing cells with changed structural relations, blood-supply of hasty construction, and tissues showing physiologic variations multiplying rapidly with small powers of resistance and slight reparative power. If such tissue be subjected to quantities of radiation correctly prescribed and administered, it will undergo tissue death either slowly or *en masse* according to the degree of rapidity with which the dose has been administered. Small doses of radiation, or radiation of so high a penetration that but little is absorbed, may on the contrary only stimulate and irritate such a lesion, and instead of producing beneficial results is prone to be followed by exacerbation of the growth. Relatively enormous doses are sometimes necessary, and the physician who desires to employ radiotherapy should have the ability to recognize the necessity of such doses and the necessary skill and apparatus for the prompt administration of them when required. In one case which I shall show in which the result was very satisfactory, it was necessary to administer on several occasions 800 times the customary dose at a single sitting, since the ordinary dose merely stimulated the disease. The treatment of skin carcinoma and epithelioma has undergone a decided change in the last few years. The aim of the successful roentgenotherapist at present is to produce a curative reaction as promptly as possible. He no longer hesitates with tentative doses but boldly proceeds to administer promptly quantities of radiation carefully predetermined that are followed by prompt results.

We frequently see cases of epithelioma about the face near the eyes that have been treated for periods of months by men of slight experience whose timidity has compelled them to attempt small doses perhaps daily instead of a few real treatments. The result is usually a chronic ulceration in a markedly atrophic area, sluggish and almost impossible to treat by any other means than excision. These are the cases in which "the x-rays have been found unsuccessful," but the failure in obtaining results is not to be wondered at. It would, however, be remarkable if favorable results were obtained under such circumstances. The treatment of superficial lesions, therefore, has been accomplished by the rapid administration of a sufficient quantity and quality of radiations to produce a reaction sufficiently intense to be followed by the

ordinary healing process, and that this is possible in the hands of any man who is willing to devote sufficient time to become familiar with the necessary technic should not meet discussion or doubt. The results obtained in superficial malignancy, lupus, rodent ulcer, etc., are not excelled by those obtained by radium or any other means of treatment.

In the treatment of deep-seated conditions an entirely different technic is necessary. In the treatment of inoperable or recurrent malignancy, a certain amount of inhibition of the growth, sometimes quite marked, may be expected to follow rational treatment. Rays of penetration sufficient to reach to the uttermost borders of the growth must be employed, tubes giving a large proportion of highly penetrating rays are necessary, and filtration sufficient to absorb all rays of slight penetration is imperative. If the sole-lead filters of Pfaliler are employed in conjunction with one or more millimeters of aluminum, large quantities of radiation may be applied with but little deleterious effect on the skin if the tubes are placed at a distance of 8 or 10 inches from the surface. Under such circumstances, large masses of tuberculous glands have been rapidly resolved at the hands of many reporters, interesting results may be obtained in cases of Hodgkin's disease and various forms of leukemia, and pituitary struma may be inhibited to a marked degree. Mediastinal involvement in malignancy has been controlled in my hands as well as in the hands of many other men for periods of one or more years.

The value of postoperative radiation as a measure of insurance against the recurrence of malignancy following operative procedure is a question that is still under discussion; I am convinced that it possesses decided value, although such a statement undoubtedly does not admit of positive proof.

The so-called deep therapy of gynecologic lesions is attracting marked attention abroad. In these conditions in which the induction of an artificial menopause is desired and contra-indications to surgical procedure exist, treatment with highly penetrating radiations through selected portals of entry with measured doses is capable of producing cessation of hemorrhage and even of ovarian function. Such treatment demands the highest degree of roentgenologic skill and technic since the doses necessary are so large as to be capable of the most destructive effects on the skin. Attempts at this technic by those who are unqualified will be certainly followed by such a series of disastrous results as to cast discredit on the whole subject of Roentgen therapy.

The Coolidge tube, an American invention, the product of the genius of Professor Coolidge of the General Electric Company, opens a new field in Roentgen therapy. This tube differs decidedly from the ordinary Roentgen-ray tube. Briefly, the cathode consists of a spiral of tungsten placed about $\frac{3}{4}$ inch from a heavy tungsten target. Both these tungsten elements are mounted in an ordinary Roentgen-ray bulb which is then exhausted by a special series of processes to an almost perfect vacuum. In this condition the tube permits the passage of no electric current, and in order to render it operative it is necessary to heat the tungsten spiral by the passage through it of an electric current of 12 volts from a storage battery. The storage battery, rheostat, ampere-meter and tungsten spiral form an electric circuit. The incandescence of the spiral is controlled by permitting the passage of more

or less current by means of the rheostat. This storage battery circuit is carefully insulated, and on the storage battery circuit there is impressed a potential of from 50,000 to 100,000 volts from a high-tension transformer, whereupon tungsten electrons from the incandescent spiral are hurled across the gap in the vacuum, striking on the tungsten target, and from the points of impact Roentgen-rays are emitted. This tube permits the passage of enormous quantities of current for long periods of time, resulting in the emission of great quantities of Roentgen rays. The penetration of rays depends entirely on the voltage impressed on the tube circuit, and if this be kept constant, the penetration remains constant. There is thus placed in the hands of the roentgenologist an instrument of precision and of extreme power, but it must be remembered that he is dealing with a two-edged sword. It is greatly feared that the introduction of this tube will be followed by a series of grave accidents, both to the roentgenologist employing it and to the patients who may be subjected to its use, unless exceeding care in technic is scrupulously followed. The employment of aluminum filters of at least 3 mm. thickness is advised when this tube is used for deep therapy.

The excitement occasioned by the discovery of large bodies of radium-bearing ores in the United States has been followed by an increase of interest in the use of this element for the emission of radiations of therapeutic value. There is no longer any doubt of the distinct value of radium rays under certain circumstances in the treatment of certain malignant conditions.

In my opinion, the greatest field for radium therapy lies in the treatment of malignant conditions in the otherwise inaccessible portions of the body, carcinoma of the esophagus, of the body of the uterus, of the bladder, of the tonsils and antrum, and in the treatment of giant-cell sarcoma in which it is possible to introduce tubes having a heavy radium content into the body of the growth by surgical means and permit the radium to remain for considerable time. Radium will by no means supplant the Roentgen ray in the treatment of these conditions, but will rather supplement such treatment as the Roentgen ray in its turn so ably supplements scientific surgery to-day. A most interesting corollary is observed in the successful treatment of the malignant keratoses produced on the hands of the roentgenologist by long exposure to the Roentgen ray. In a number of instances which I have observed, fingers which demand amputation on account of multiple malignancies have been saved by the application of radium and are now covered by apparently normal and healthy epithelium. The explanation of this fact is not yet clear.

SUMMARY

1. The Roentgen ray is of distinct value in the treatment of a number of conditions.

2. It can never supplant, but can and does supplement, surgery to a valuable degree.

3. The results to be expected depend on the employment of a correct technic which implies the ability to prescribe correctly and administer the necessary dosage at the necessary time in each individual case.

4. The Coolidge tube has placed in the hands of the profession an instrument capable of great good if carefully and intelligently employed.

5. The value of radium as a therapeutic agent should be no longer disputed.

6. The physician employing these various agents must be thoroughly familiar with the possibilities of present-day surgery as well as expert in his own technic in order that his patient may obtain the benefit of everything that science has to offer.

7. Physicians and the public must never forget that every case of malignancy remains for a certain length of time after its inception a curable disease by proper surgical procedure.

Jenkins Arcade.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. NEWCOMET AND JOHNSTON

DR. HENRY K. PANCOAST, Philadelphia: A most important difference between Roentgen rays and the "gamma" rays of radium, is in their manner of production. "Gamma" rays are produced at the time of disruption of the atom, and Roentgen rays at the time of impact of the negative corpuscle, hence the greater and more uniform degree or penetration of the "gamma" rays. All roentgenologists realize that we are again in a developmental stage with roentgenotherapy, and that in the next few years much more will be accomplished, especially in deep treatment. This will be brought about mainly by the combined use of the Coolidge tube, cross-fire radiation and adequate filtration. In the treatment of superficial lesions, everyone now employs massive dosage, one or a very few applications being all that is necessary to control the disease. If this principle is applied to deep lesions, and a massive or erythema dose is directed at the site of the growth by cross-fire methods, similar results should be obtained in many cases. One of the most important applications of deep therapy is in the treatment of uterine fibromas. Results may have been such as to substantiate the claim for this as the preferable method of treatment, but I can hardly accede to such a view at present. I still believe that roentgenotherapy should be reserved for selected cases in which radical operations are undesirable, refused or contra-indicated. Much can now be accomplished even in uterine carcinoma. Finally, while roentgenotherapy will never be a panacea for deep-seated cancer, we feel sure that future results will surpass those of the past.

DR. ARTHUR F. HOLDING, New York: The application of radium as we find it is confined to small areas. The tubes are small and can only be applied to small areas and in order to treat large areas the method of emanations in vacuum tubes is possible. This is an important advance in the use of this radium for malignancy. I think there was no mention made of the use of the emanations for constitutional diseases. The results of radium are usually obtained in the treatment of superficial lesions but Van Noorden and others have used it in many other conditions, using the emanations in a closed chamber. Very little work of this kind is done in this country. We must consider both the local and general reactions of radium. So far as we have gone now we use both of these agents in the same class of patients. As we have more experience with these two agents we can use them according to the case. Those who have had the most experience with the Roentgen ray think most of it and the same holds true of radium. The most important thing to recognize is that there are certain classes of cases that can be adequately handled by any one of these agents: it is not the question whether one is better than the other. You can get a better cosmetic result without opening lymphatics, etc., by these physical methods. The Roentgen rays were discovered in 1895 and we are just beginning to think we know a little about this agent. We do not know as much about radium and in order to find out we must cooperate with the physicist. At present radium is difficult to obtain. The Roentgen ray and desiccation do very well in the same class of cases as the radium. Care must be used in selection of cases for treatment with radium or the Roentgen ray. The

Roentgen ray has a great deal of power for superficial healing and therefore care must be taken in its use. Sometimes there is marked healing and everything pathologic that is visible disappears under the radium, but the patients develop marked cachexia. There is danger in attempting too much.

DR. WILLIAM DUANE, Boston: It has been discovered that the Roentgen ray from a tube really consists of two different kinds of ray. The penetration of one kind depends on the voltage, and the penetration of the other depends on the substance used as an anticathode. Roentgen rays have been found to be similar to the ultraviolet light, although for seventeen years it was thought that they were quite different from ordinary light. It has recently been discovered that Roentgen rays are light waves of exceedingly short wavelength. The shorter the wave the more penetrating it is. It has been shown that the wave-length of the Roentgen ray depends on the nature of the anticathode in the tube. I want to emphasize the fact that the rays from the tubes are of two kinds, one depending on the voltage and the other on the nature of the anticathode.

DR. A. L. GRAY, Richmond, Va.: I have had no experience with radium except some years ago in treating one or two tumors on which I was using a very small amount and of low radio-activity. I obtained no results with the specimens I used. I have now been actively engaged in Roentgen therapy for some twelve years, and my results are as good as if not better than at first and my enthusiasm has never waned in the slightest. I have not been employing deep therapy except in the treatment of tuberculous adenitis. My results have been almost uniformly good in these cases by the fractional method of treatment. I am now using massive dosage, and have been for a short time, but I can not yet definitely report results. Those who have been for some time employing the massive-dose method report that they are experiencing better results from it than they formerly did by fractional dosage. It is more satisfactory to the patient as well as to the operator, and the end-results, so far as I know, are equally as good as if not decidedly better than by the fractional method.

DR. JAMES W. HUNTER, Norfolk, W. Va.: Has anyone had any experience in deep therapy with the Coolidge tube and if so, does he employ filters? I have tried some work on deep therapy with excellent results but I do not encourage it very much. I should also like to ask about the use of filters of thin sheet lead used in the same manner that radium is employed.

DR. GEORGE E. PFAHLER, Philadelphia: I have been interested in the deep therapy and have been using the Coolidge tube a great deal and am enthusiastic in its use and results. It is exact and capable of delivering anything we wish. We can give enormous doses in a short time and it enables us to multiply our fields of entrance so as to give a single dose through any part of the skin and yet multiply the deep effect as many times as we wish according to the time and energy we wish to put on the patient. We have to-day an agent that is, I would estimate, one hundred times more valuable in the treatment of deep-seated diseases than we had at hand a year ago. We cannot report wonderful cures at present, as a sufficient time has not yet elapsed. We have the right to expect results we have not heard of before. We cannot cure all cancers no matter what we do, but I believe we can increase our end-results very much within the coming year. I refer to one case as an illustration of what can be accomplished by the newer technic. Dr. Barton Cook Hirst operated on a woman in May, 1913, and found the entire viscera matted together by carcinoma. The abdomen was closed and the patient developed progressive symptoms of obstruction of the bowel and intense pain requiring morphin. The family physician sent the patient to the dispensary under my care with a note asking me to give her treatment, for a mental effect, and possibly for the relief of pain. I said I was willing to try what could be accomplished and I therefore at once divided the abdomen into thirty-five areas and sent through thirty-five full doses (that is, all the skin could stand). Therefore, the deep part of that disease got thirty-five times as much as we could have given this patient a few

years ago. I should add that I repeated this dosage in two weeks and in several areas got rather a severe burn of the skin. I believe we should never repeat it in two weeks and probably not in less than three. This treatment begun in December. I sent her back for examination a week or ten days ago and the only evidence of the former disease was a little resistance in the left iliac region; all the rest is soft and the patient is enjoying good health. This is thirteen months after she was given up as hopeless. This will serve as an example of what we probably can hope for in the future and which we could not do in the past.

DR. G. B. MASSEY, Philadelphia: Probably the most useful result of Dr. Johnston's showing and of Dr. Pfahler's case is to offset rather a bad impression prevalent in the medical profession as to the inefficacy of the Roentgen ray in cancer. I hear a great deal of discouraging talk about it. It is my belief that the cause of a great deal of this is the inefficiency of the operator. The Roentgen ray is used too carelessly. It is used by men who do not look after their work properly, delegating it to nurses, and by those who do not know what they are doing themselves. It is also true, as Dr. Pancoast says, that each of us has his own method, in which he is most efficient, though there may be several ways to treat some of these cases. While it is very true that the progress of the future will depend largely on the development of personal efficiency in definite methods, an equally important thing is to realize that there should be a selection of methods that are really best in given varieties and stages. It may be that the method we use is not the best in a particular case. To me, for instance, it is absurd to use the Roentgen ray or radium for a small epithelioma of the skin no larger than a pea, and flood the body to an unknown depth with this force, when in ten minutes it could be destroyed by ionization or desiccation. As far as I know the use of the Roentgen method in the mouth has been ineffectual in growths of the mucous membrane; here we have a vast field for the ionization process. We must cultivate the several varieties of the physical forces as they are developed and applied in this work as well as our own efficiency; the best results are by the combination of both.

DR. WILLIAM L. CLARK, Philadelphia: I am convinced that the massive-dose, cross-fire method of applying the Roentgen rays is more productive of results than the small divided-dose method, especially in the case of malignancy. I believe that the Coolidge tube offers great possibilities on account of greater penetrating power and refinement of control. It has been declared that on account of shorter wave-lengths, the gamma rays of radium may be approximated or even duplicated. If this is true, the whole range of Roentgen ray and radium effects could be produced at will, and the whole subject revolutionized. Since the "desiccation method" has been mentioned several times in the discussions I may briefly allude to it. I have depended on desiccation entirely in the superficial epitheliomas, but in more advanced cases the efficiency is increased by employing the Roentgen rays in conjunction. I have found that as much can be immediately accomplished by one desiccation application as can be accomplished by the Roentgen rays in a comparatively long period of time, but in combination the efficiency of both is increased, doubtless due to the action of the Roentgen rays on pathologic tissue deeper than can be reached by desiccation.

DR. GEORGE C. JOHNSTON, Pittsburgh: I do not claim that the Roentgen ray is the cure for cancer. Every case of malignancy in its inception and for a certain length of time following is a curable disease by surgical procedure if it is possible to remove the disease completely. Every man who practices roentgenotherapy should associate himself freely with a competent surgeon so that he may know what surgery can do and hence will not deprive his patients of proper surgical procedure. When surgery does not prove successful or in certain locations such as the eyelids, for example, when better results may be obtained by radium or Roentgen ray, we are justified in using these agents. There is no difficulty in obtaining radium if one will pay the price for it. Nine-

tenths of the radium reports mean nothing because they do not specify the amount of radium element employed. In this country, at present, a great many men are working with tubes containing what they believe to be radium and for which they have paid a radium price but which really contain little, if any, radium element. I believe that radium has a distinct use, especially in locations which are inaccessible to the Roentgen ray, and there is no doubt in my mind that excellent results can be obtained if proper quantities of radium element are intelligently employed. Radium is a necessity in the treatment of chronic Roentgen dermatitis seen on the hands of roentgenologists. There is no other agent that will produce the results obtained by radium in the treatment of these conditions. The Coolidge tube contains no positive ions. If a Coolidge tube fluoresces green, it is not properly pumped and is not a Coolidge tube at all.

DR. WILLIAM S. NEWCOMET, Philadelphia: I am not interested in the superficial conditions such as epithelioma of the skin because they can be effectively treated by many other methods. While many good results are observed in these deep malignant diseases, these radio-active elements must not be regarded as a "cure all." Formerly 1 mg. of radium salt might be spoken of as having 1,800,000 activity, and another specimen as having 600,000 activity, while the weaker specimen might contain more radium and would actually be a better specimen, as the methods of measurement were very crude. It makes very little difference whether you have 10 or 20 mg. in a given specimen containing the same amount of radium, as the high beta and gamma radiation easily penetrates the debris, and the filtration used is often 3 mm. of lead, which far exceeds the natural filtration under these circumstances. No doubt many of these persons who were supposed to have been deceived a number of years ago, bought the supposed radium at the actual strength, but it contained a mass of thorium products which degenerate rapidly, and made these specimens in a couple of years decidedly weaker. The dealers must not be censured for it, however, as it was a matter of ignorance and not deceit. One condition in which radium far supersedes the Roentgen ray in that of nevi. By means of radium and without leaving a scar I removed a large cavernous nevus from a child who in addition had a greatly enlarged nose. I do not believe this could have been accomplished by the Roentgen ray or by acupuncture of the days gone by. My enthusiasm over radium is partly due to the conditions which yield to it when the Roentgen ray fails. With relation to the position of the Roentgen ray I think that some cases are more easily handled by surgery and the results are better; but in conditions allied to superficial skin epithelioma of slow type the Roentgen ray is to be preferred for the cosmetic result; no tissues are injured and after the lesion is once healed it usually remains permanently healed.

EPITHELIOMA OF THE LIDS*

CARL FISHER, M.D.

ROCHESTER, MINN.

Epitheliomas of the lids require some consideration apart from epitheliomas of the skin elsewhere, because of their proximity to the orbit and sinuses and because of the disastrous effects of destruction of the lids on vision and on the appearance of the patient. A good proportion of these patients do not consult the ophthalmologist but are sent to the general surgeon after a long course of salves, pastes and Roentgen-ray treatment.

I have been able to study eighty-eight cases of epithelioma primary in the lids and canthi, or involving

them from the skin in the immediate vicinity (nose, cheek, brow), having chiefly in mind the prognosis of operative treatment. The statistical data were collected to serve as a basis of comparison with other methods of treatment, especially radium. It should be added that the diagnosis in all cases was confirmed by microscopic examination.

The epitheliomas of the lid all belonged to the type known as basal-celled, or, to use a rather popular term, rodent ulcer. By this is commonly meant clinically a cancer of the skin of very slow growth, with no tendency to glandular metastases, spreading by continuity, and usually ulcerating as it progresses. Pathologically, it is somewhat more difficult to define, though this is perhaps of no great consequence to our present object. Adami¹ sums up the present view of this class of epithelioma.

Krompecher, recognizing that all conditions classified as rodent ulcer do not belong to the type, has labeled this form basal-celled carcinoma, on the mistaken ground that, as it shows no prickle cells nor keratinization, it is derived wholly from the basal, undifferentiated cells of the rete Malpighii. But this is so also for all epitheliomas. In the more highly developed forms the prickle cells present do not arise from pre-existing prickle cells, but also from basal mother cells. It is the stage of undifferentiation and anaplasia—the capacity to develop beyond a certain point—that determines the form of the cells.

After the growth has progressed, both basal and squamous cells are to be found in the field, one or the other predominating. Sometimes the appearance may closely simulate sarcoma from the tendency of the epithelial cells to assume spindle forms. I have seen this mistaken diagnosis made several times in epitheliomas of the orbit (Figs. 1 and 2).

In this series the average age of incidence was 53 years. The youngest patient was 24 years old. The average patient waited five years before coming for treatment; many of them from fifteen to twenty-five years; these latter mostly began as keratoses and small wart-like nodules. Some developed rapidly, that is, in one month.

The favorite points of origin were the lower lid (46 per cent.), the inner canthus, over the lacrimal sac (36 per cent.). The next most common point of origin was the upper lid and, least common, the outer canthus.

Of the cancers of the lid, considerably over half originated in the skin of the lid just away from the cilia, the others starting indifferently on the very margin of the lid or the base. There seems to be no obvious reason why the lids should be so favorable a site for the development of epithelioma. The fact that the lower lid and inner canthus are so much more commonly affected might be attributed to the irritation caused by tears and foreign matter. Certainly these regions are usually hyperemic when the upper lid and outer canthus show comparatively little evidence of irritation. In only one case was the pressure from eye-glasses a probable source of the initial irritation, which is so commonly looked for. The type of skin well recognized as a fertile soil for epithelioma—a dry, rubicund skin, seen most often in blond people exposed to the elements—was very often seen, but by no means predominated.

The majority of these cancers progressed by invasion only, the first step being attachment to the peri-

* Read before the Section on Ophthalmology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

* From the Mayo Clinic.

1. Adami: General Pathology, Philadelphia and New York, 1908, p. 735.

osteum of the orbital border, then progression into the orbit and conjunctiva. In several cases the inner orbital walls were destroyed. Occasionally the antrum was involved, and more often the ethmoids, rendering successful operation very difficult.

In five cases, cervical or parotid glandular involvement was present when the patient was first seen. These two groups of glands drain all of the skin and the conjunctiva, while the orbit drains into the internal maxillary group and thence into the deep cervical. Unsuccessful treatment seems to favor glandular involvement, since, of these five patients, only one had escaped pastes or Roentgen rays previous to examination in our clinic, and about the same proportion was found in epitheliomas of the cheek with glandular involvement. The type of tumor did not differ microscopically in these cases from that in cases not showing glandular involvement, so that the failure to involve glands is not a necessary characteristic of rodent ulcer. Our pathologic records, however, do not indicate the character of the metastatic growth. None of the patients developed enlarged glands after coming under our observation, which may have been due to the methods of treatment employed.

Fig. 1.—Epithelial down-growth showing spindle and oval cells which, when in masses, often look like sarcoma cells.

These patients were treated chiefly in three ways—radical excision, excision with actual cautery of the wound, or simply actual cautery, the method employed depending on the site of the growth and the degree to which it had progressed. Purely cutaneous growths, if small, were cauterized. Growths involving the border of the lid, but not adherent to the periosteum, were excised and a plastic operation done to restore the lid. Where the growth was adherent to periosteum or had involved conjunctiva and orbit, or tear-sac, actual cautery was added to excision. In cases of orbital involvement not readily accessible, an exenteration of the orbit, including the periosteum, was performed and the contents of the apex cauterized. For cauterizing large areas, the soldering iron was found preferable on account of the deep cooking given the tissues—a principle used in Percy's treatment of cancers. Involved sinuses were opened, curetted and cauterized in so far as possible.

The plastic repair of the lower lid is a frequent problem. Many satisfactory results were obtained from the transplantation of a "hammock" flap of skin from the upper lid, a method devised by C. H. Mayo. This flap is soft, of the same color as the normal lid, and grows readily. The operation recently described

by Gibbon² promises to be the one of choice when the lower lid has been largely destroyed. No conventional method will serve every case. The repair is easy when a fair amount of the lid has been left. When, however, the entire lid and part of the cheek have been removed, as is often necessary, large flaps from the temple (as noted in the text-books) give the best results. The Dieffenbach and similar procedures, beautiful on paper, have not proved so successful on patients.

RECURRENCES

This has no reference to final cures, but refers to any recurrence whatever taking place after operation in our clinic. Most of these were small nodules, easily burned off. Of the thirty-three epitheliomas involving the lids and canthi alone (adherent or not adherent), 17 per cent. recurred at some time. These recurrences were all at the site of the previous growth, and not in glands. When, however, the growth had penetrated the orbit, the percentage of recurrence rose rapidly—eight out of eleven. Of thirteen cases involving the orbit, primarily and secondarily, three have passed the one-year period without recurrence. Four others have not yet recurred, but have not gone a year since operation. The time-limit of one year is somewhat arbitrary, but is based on the average time before recurrence, namely, nine months. This is a rather high average, being brought up by a few unusual cases which were reported as having recurred very late. The majority of cases which recurred at all did so in three to four months.

The chief interest in these cases for the clinician lies in the ultimate prognosis. I have not counted as cures cases of less than one year's standing since the last operation or treatment. Naturally, the percentage would be considerably higher if cases of over four months' standing were cited and if all patients were willing to return at the first sign of recurrence.

Of the thirty-three epitheliomas of the lids and canthi, not including the orbit, in which the records have been completed by recent news of the patients, 94 per cent. were cured by operation. When the orbit was involved, the percentage was turned about; 80 per cent. were not permanently cured. These include cases in which the sinuses also were involved. The factors which mitigate against cure are: inner canthus involvement, penetration of conjunctiva or lacrimal sac, orbital involvement and sinus involvement. The cases of glandular involvement cannot be classified because our records are not completed, owing to the lack of recent information of these patients. The one "completed" case had no recurrence after a radical local removal, and dissection of the cervical glands.

The comparison of these results with those obtained by the use of radium or Roentgen rays or pastes is difficult because of the absence in most papers on the subject of definite data regarding the duration of the cure. Williams and Ellsworth, however, are not remiss in this regard.³ Of the nineteen cancers of the skin of the lids, two-year cures are reported in thirteen cases, or 68 per cent. These are evidently not intended to include cases with orbital involvement, since one case of orbital involvement is listed separately. The percentage of two-year cures by operation in our series was 84.

2. Gibbon: Blepharoplasty by a Pregrafted Flap, read before the American Surgical Association, April 9, 1914.
3. Williams and Ellsworth: Treatment of Superficial New Growth by Pure Radium Bromid, THE JOURNAL A. M. A., May 31, 1913, p. 1694.

Pinch,⁴ in a report of the Radium Institute of London, classified his cases of rodent ulcer into apparently cured, thirty-one; "improved," forty-one; not improved, twelve; abandoned treatment, six. Counting improved, not improved and abandoned as failures (as was done in our series), the percentage of cure is far from satisfactory (about 39 per cent.) and this without any minimum time-limit set. It should be said, however, that these were rodent ulcers of various regions and severities, so that the comparison is not altogether fair. Pinch was able to state on this showing that "rodent ulcer is of all cancers the most amenable to radium treatment." Turner⁵ cured six out of nine completed cases of rodent ulcer of various parts of face and lips, or 66 per cent., time not stated. The best opinion at present concerning radium versus operative treatment of these cases is well-summed up by Knox.⁶

"1. In all cases of early cancer, the operative method is undoubtedly best; it is quicker, safer and offers the best prospect of cure. . . . 3. In patients who refuse operation or are otherwise unfit for operation, radium is a useful remedy."

Fig. 2.—The same as Figure 1, except growth is taken from nose.

Comparison of operative treatment with pastes is also difficult. I have found no recent records sufficiently exact to afford a statistical comparison. Perhaps the most revolting, because easily avoidable, pictures of malpractice that one sees are cases of cancer of the skin treated with various pastes, and the inevitable impression received is that the public has suffered unspeakably from the exploitation of the paste treatment. Nevertheless, it must be acknowledged that in the hands of persons practiced in this procedure, many surprising cures are obtained, and these sometimes in apparently inoperable cases. No doubt the continued financial success of certain "cancer institutes" is maintained by a fair number at least of noteworthy cures.

The Roentgen ray is believed to owe what efficiency it possesses to a ray corresponding to the gamma ray of radium, so that there seems to be no reason for preferring it to the latter (save its greater accessibility) since the curative rays are acknowledged to comprise only a small part of the whole Roentgen ray. In point of fact, the Roentgen ray cannot be regarded as a

dependable agent in the treatment of epitheliomas, however useful it may be as a palliative or postoperative measure.

The present evidence seems conclusive that operative measures are, in general, the safest means of treatment we possess for epitheliomas of the lids (and for that matter in any other region), and especially when the growth is rapid and adherence to periosteum or involvement of the orbit has taken place or evidently will soon take place. On the other hand, when the patient can be kept under observation until a cure is completed and the growth is proceeding slowly, there seems to be no good reason why radium should not be used. In cases of this kind, however, it has the disadvantage of slowness, and there is also the difficulty, in most places, of obtaining the radium. But many patients prefer any amount of treatment to the use of the knife, a psychological factor that is heavily featured in the advertisements of the clever charlatans. The cosmetic results of successful radium therapy are excellent; I have seen no injury or reports of injury to the eye from its use; it is practically painless. In this as in any therapeutic or surgical measure, the experience and ability of the physician in charge plays an important rôle, especially in pioneer work with comparatively new methods of treatment.

The importance of early and radical operation in epitheliomas with orbital extension is well emphasized in the statistical data given above. Unless the growth is so clearly circumscribed that complete removal without sacrificing the eye is certain, a complete exenteration of the orbit followed by cautery is imperative. Extension to the sinuses renders the prognosis nearly hopeless; in such cases, if operation is decided on, it should be followed by the persistent use of radium or by Roentgen ray if the former is not available. Glandular involvement, without orbital extension, does not necessarily indicate a bad prognosis, granting that a proper resection of the gland-bearing fascia be made.

ABSTRACT OF DISCUSSION

DR. EDWIN E. JACK, Boston: My own experience with epithelioma of the lids, never in any way comparable with Dr. Fisher's, has been smaller in recent years and offers nothing from which statistics of value can be drawn. It has seemed to me that such cases went more and more to the general surgeon or for Roentgen-ray and radium treatment. The public print too has been busy with this, as with other new subjects in medicine, and it is likely that many choose their own method of treatment—and it is not that by the knife. It seems impossible to disagree with Dr. Fisher in any of the statements he has made. If patients with epithelioma involving the sinuses recover under any treatment I do not know of them. Penetration into the orbit, involvement of bone, situation at the inner canthus—all undoubtedly influence the prognosis for the worse. The surgical technic described by Dr. Fisher represents the last word. From the cosmetic point of view, in any advanced case, of course operation leaves much to be desired, for it is often true that space must be filled in as best we can. In the less serious cases, deformity is less, but the results rarely resemble the almost marvelous ones of successful radium therapy. The greatest point of interest in connection with the subject is the relative value of this therapy and of operative treatment. We have all of us undoubtedly seen cases of small epithelioma beautifully cured by the Roentgen ray and radium, and have seen or heard of authentic like results in larger growths, even in some which offered little hope from an operative point of view. We have, in addition to our own experience in this matter, that of surgeons, roentgenoscopists and radiographers

4. Pinch: Brit. Med. Jour., Jan. 25, 1913, p. 149.

Cornell University, New York City, in a report presented to the Section on Dermatology, classified desiccation surgery as the method of choice for localized epitheliomas. The realm of surgery is a wide one in which desiccation plays only a small part, but in localized epitheliomas and precancerous lesions, such as moles, nevi, etc., especially those of the lids and canthi, there can be but one choice for those who have compared the results of both excision and desiccation.

DR. CARL FISHER, Rochester, Minn.: I wish to reiterate that no one would attempt to insist on any one treatment for lid cancer. There are so many conditions to be considered—the distance the patient lives, his own particular conditions of living, what method the surgeon has had experience in using, accessibility to radium, etc. I do not think that any one would say that all cases should be operated on or that all should have radium. Since Dr. J. F. Percy began treating large uterine cancers with heat below the point of carbonization he has done some wonderful work, and it strikes me that the use of heat below the point of carbonization would be effective in all these lid or superficial cancers, just as it is effective in the deeper-seated cancers. This I have not done in a large enough series to report.

A STUDY OF THREE HUNDRED CASES OF APPENDICITIS WITH SPECIAL REFER- ENCE TO PELVIC COMPLICATIONS*

ARCHIBALD MACLAREN, M.D.

ST. PAUL

I have taken for this study 300 cases of acute suppurative appendicitis, excluding all chronic, subacute, relapsing, and acute cases in which no pus was found. This is a consecutive personal list in which I have not included patients operated on by any of my three partners or by any of my assistants at any of the hospitals with which I am connected. Over 12 per cent. of these patients were operated on in farmhouses or country hospitals, and many of these have been my very worst cases, the patients being so sick that the family physician would not dare to move them. I feel sure from my experience that the cases which reached the metropolitan hospital from the country districts are always to a certain extent selected, and the best cases from an operative point of view.

In this study the especial interest to me has centered about pelvic rectal drainage and its influence on the mortality rate. Rectal drainage in these bad cases was original with me when I first used it, although I later discovered that it had been advocated by McNaughton, Stillman and others, whose publications I had never seen until I had operated on my first eight patients, whose cases were reported five years ago before the American Surgical Association.

I first tried to follow the ordinary method of dividing the perforated-appendix cases into two classes, general septic peritonitis and local appendiceal abscess. I soon discovered, however, that I could not make this distinction with certainty in border-line cases, either before or after operation.

It has been a matter of habit with me in keeping my personal records to note the approximate quantity of pus in each case, and this fact gives me an opportunity to make a division of my cases on this basis, which I believe is one of true value in determining the prognosis. The quantity of pus in a certain case is of great importance. The operation for opening a large

abscess is much more dangerous, at any stage of the disease, than the same operation on a small accumulation of pus entirely aside from its virulence. I have arbitrarily designated 4 ounces as the dividing line for the reason that it is unusual to see a single localized abscess contain a larger quantity. When the quantity obtained is larger than this, there is usually a secondary abscess or involvement of the free peritoneum so that large abscesses can best be grouped with general peritonitis cases for this study.

I have taken 150 consecutive cases before my first rectal section and 150 consecutive cases since that time for a basis of comparison. In the first 150 cases there were 13 deaths, divided as follows: in 61 general peritonitis and large-abscess cases with four or more ounces of pus, 12 deaths; in 34 abscesses with less than 4 ounces of pus, 1 death; in 55 cases without rupture, either gangrenous, or appendixes, containing pus, no death.

Fig. 1.—Normal midline section left half of pelvis.

In the last division I wish to say that most of these are the acute cases in which the patients are operated on in the first 48 hours of the attack. If the appendix was accidentally ruptured during the removal, the case was included as unruptured. The general mortality, then, is 8.6 per cent. During this same period operation was refused in three fatal cases in the hope that they would safely reach the eighth day (Ochsner). It seems to me that these should be added to the mortality list, which would raise the mortality to 10.6 per cent.

In the second series of 150 cases with operation since the use of rectal drainage, there were 7 deaths, disposed as follows: in 84 general peritonitis and large abscess cases, 7 deaths; in 32 small abscess cases, no deaths; in 34 unruptured, gangrenous and appendixes containing pus, no deaths. This brings the general mortality to 4.7 per cent.

In this second list there were 84 cases classified as general peritonitis as against 61 in the first list,

* Read before the Section on Surgery, General and Abdominal, at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

and there seems to be a corresponding fall in the unruptured cases, from 55 to 34. This may be due to the more general use of the Ochsner treatment or to the suspicion of the laity, created by many so-called surgeons who have been rushing to the hospital every kind of case from typhoid to ptosis. The second series includes many more desperately sick patients than the first, yet the mortality rate has been cut in

Fig. 2.—Small abscess in culdesac; right half of pelvis.

two by what I believe to be a life-saving surgical procedure.

The question may be asked, What relation has rectal section to these seven deaths? Was any death caused by rectal section?

CASE 1.—The first death occurred after a laparotomy in a very sick child aged 6, first seen on the fifth day. This little girl died in stupor, twelve hours after operation, with pinpoint pupils and a gradually failing respiration. The nurse had given two hypodermatic injections of morphin, each supposed to be 1/12 grain. The first injection had no effect, and on account of her great restlessness two hours later a second 1/12 was given, which was soon followed by death.

CASE 2.—Mr. S., aged 40; sick five days; died the day following the operation, pus having been found all through the abdomen; two abdominal drains, one in the right loin, one through the suprapubic stab.

CASE 3.—Child, aged 7, very ill; first seen on the fifth day with marked pelvic abscess bulging through the anterior rectal wall. Rectal section and letting out a half-pint of thin serous pus; this child was so well for the next three or four days that she was considered out of danger. On the seventh day after the operation she was very sick again; a laparotomy disclosed another large accumulation of pus in the right loin. The laparotomy in this case should have been made on the second or third day after the rectal section. This child died two days following the last operation.

CASE 4.—S. J., aged 25; operated on forty hours after perforation. Drain through the stab just outside of the cross-muscle incision; died on the seventeenth day from general septicemia associated with an erysipelatous inflammation of the abdominal wall and back starting from the incision. Since this case I never use the cross-muscle incision in pus cases.

CASE 5.—Mrs. G., aged 63; operation in farmhouse; sick six days; supposed by her physician to be suffering from renal calculus; vomiting fecal in character for forty-eight hours; laparotomy; general septic peritonitis; two rubber tube-drains, one in the loin and one suprapubic stab into the pelvis; died in a few hours from shock.

CASE 6.—J. O., aged 27; sick thirty-six hours; laparotomy; tube-drain into culdesac. On the eleventh day a rectal sec-

tion was made; quart of pus; death same night: In this case the rectal section was delayed too long. It seems to me that with greater care both this patient and Patient 3 should have been saved.

CASE 7.—G. L., aged 45; sick eight days; operation in a farmhouse; laparotomy; drain in right loin and rectal drainage; did not rally from the anesthetic.

In the first 150 cases there were six deaths; these six cases from their histories, seem to me now to have been suitable for rectal puncture. Three of this number were examined post mortem and the pelvis was found full of pus. The one case which particularly stimulated me to the use of this procedure was that of a boy who died, complaining bitterly because the nurse was inattentive to his bowels and would not bring the bed-pan as frequently as he desired. After death the sphincter was found dilated to an inch in diameter by the anterior wall of the rectum, pressed down by a large pelvic abscess. Thereafter I never considered an examination of any inflammatory abdominal condition complete without a rectal examination.

At first the operation of rectal puncture and drainage was confined to cases in which there had previously been operations for acute appendicitis. The accumulation in the culdesac would generally show itself by night pain, rise in temperature and pulse, and commencing septic appearance about six days after operation. Many times the culdesac was found distended with pus, even when a large-sized rubber tube extended from the wound or from an anterior-wall stab into the culdesac.

Fig. 3.—Method of opening small pelvic abscess; scissors used to puncture abscess and as dilators.

The reason for this is that intra-abdominal pressure exists at maximum only, when there are no peritoneal adhesions, and that as the adhesions increase in amount and strength the intra-abdominal pressure rapidly decreases to zero. I have several times seen cases, say, ten days or two weeks after operation, in which the drainage wound above was pouring out a perfect stream of pus, while the patient was rapidly losing

ground, owing to septic absorption from a large pelvic abscess. Rectal section in these cases has quickly worked marvelous changes. In one case of this type, a boy seen at the University Hospital, who had a temperature of 102 every night, and was vomiting and so sick that he could not eat, was crying for food, after 2 pints of pus were removed, and this in four hours after the pus was evacuated. He rapidly recovered. After we had demonstrated the great value of this method in the postoperative cases, we extended its use to bad cases of patients seen late in the course of a perforative attack, who had not been operated on. Many of these have been young children who were first seen between the third and the sixth day, dangerously sick, with a marked distention of the culdesac. In such patients in whom the danger is of a back-firing of the pelvic abscess, with a fatal general peritonitis, the first thing done has been the making of a rectal section and the putting in of a winged rubber tube-drain. If the patient was entirely relieved, so far as

Fig. 4.—Dilatation of sphincter from pressure of large pelvic abscess through anterior wall of rectum.

pain and temperature was concerned, nothing else was done at that time, but usually the very next day, an exploratory laparotomy was done and the gangrenous appendix removed.

I believe in removing the appendix only when it can be done without adding any percentage of mortality to the operative risk. It is surprising how much more one can do toward removing appendixes, however, with added experience.

We believe that the rectal drainage is no more dangerous than vaginal section. In little girls we always use rectal section in preference to vaginal section. Up to the present time we have not used rectal section in adult women, but have continued to drain pelvic abscesses through the vagina, as has been done so successfully for so many years for all sorts of pelvic abscess.

I find that in this last 150 cases, I have considered it wise, to make a primary rectal section 11 times. Secondary to laparotomy I have opened and drained the rectum 13 times, making a total of 24 rectal sections in 150 cases, or approximately 17 per cent.

With the exception of the two patients mentioned above, all the patients of this class treated with rectal section have rapidly recovered and not one has had a fistula. In one case when a large pelvic abscess had resulted from a perforating ulcer on the anterior wall of the upper rectum, drainage through this perforation promptly cured the abscess; when at the end of eight days the winged rubber tube was pulled out of the rectum the perforation promptly closed. Proctoscopic examination in this case two weeks after the tube was removed showed a small scar where the perforated ulcer had been.

CONCLUSIONS

1. The successful treatment of acute appendicitis depends on the time when the patient can be operated on after perforation, the earlier the better.
2. We should continue to impress this fact on the laity.
3. Drainage must be complete and, for a certain percentage of cases, rectal drainage is a most efficient measure.
4. After operation has been performed we must not forget these patients. The method of attack is not so important as eternal vigilance, constant watching and frequent rectal examinations, which should be made, if in the future we are to save some who would have been lost in the past.

HAS THE LAST WORD BEEN SPOKEN CONCERNING APPENDICITIS?*

JAMES E. MOORE, M.D.

MINNEAPOLIS

In 1582 Ambrose Paré said in the preface to his surgery that he had striven so successfully for forty years to bring surgery to perfection that posterity would not be able to surpass us save by some additions such as are easily made to things already discovered—and all that we have left of his teaching is the use of the ligature.

In 1882 Samuel D. Gross, founder and first president of the American Surgical Association and the leading surgeon of his generation, said, "Operative surgery challenges the respect and admiration of the world, and if it has not attained its finality it is as nearly perfect as we can hope to make it"—and he had never performed an appendectomy.

If these men, who were the greatest in their day, were so mistaken, it would be absurd for any of us to say that the last word has been spoken concerning any topic in surgery, for it is a live subject and while the present generation can justly claim that it has added more toward its perfection than has been added in all time before, future generations will doubtless improve on it to a point far beyond our fondest dreams.

The last word has not been spoken concerning appendicitis, and possibly never will be, because the

* Read before the Section on Surgery, General and Abdominal, at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

last word can not be spoken until the mortality from this affliction has been completely obliterated. A few years ago every program for this meeting contained too many papers on appendicitis, but for the past few years they have been too few. We have doubtless all changed our views since we had our last "battle royal;" is it not time, therefore, to review and see how our present views compare? If in our discussion we find that we are nearer of one mind we shall know that we have advanced. If, on the other hand, we find that we are as far apart as ever, we shall know that there is great need for improvement and that we must renew our efforts as though the topic were a new one.

Little has been added lately to our methods of diagnosis. That syndrome, diffuse abdominal pain which later becomes local in the right lower quadrant, vomiting, local tenderness, and muscular rigidity, is one that can not well be mistaken. The average case of acute appendicitis is the easiest of intra-abdominal conditions to diagnosticate, but there are exceptional cases in which the most skilled diagnosticians may be mistaken. Within one month we have had four patients in the University Hospital who had no pain, rise of temperature or vomiting when they were admitted. The evidence on which a diagnosis of appendicitis was made was the history of pain and vomiting before admission, the presence of muscular rigidity, and leukocytosis. In all four a ruptured gangrenous appendix and an abdomen full of pus were found. All recovered, but without operation would surely have died. The most common mistake is to make a diagnosis of appendicitis when it does not exist. Not every pain in the abdomen is appendicitis. In our northern climate pneumonia is frequently mistaken for appendicitis in children. Intussusception has not infrequently been mistaken for appendicitis. Retrocecal appendicitis is now a well-recognized condition, and a positive diagnosis of this condition can usually be made by a careful observer. Muscular rigidity over the appendix is the most reliable symptom of appendicitis, and when a patient has all of the other cardinal symptoms and this one is lacking retrocecal appendicitis should be suspected; and if tenderness can be elicited by pressure in the loin just back of the cecum a diagnosis of retrocecal appendicitis is quite certain. In some cases of retrocecal appendicitis psoas contraction is a marked symptom. Refinements in diagnosis should not be undertaken before operation, because it is a waste of time and a mistake in classification may lead to disastrous delay. The time to decide whether a case of appendicitis is catarrhal, perforative, or gangrenous is after the surgeon has removed the specimen.

The prognosis in appendicitis has become better each year, but there is still room for improvement. Statistics concerning appendicitis are preeminently unreliable, but it has been quite generally accepted that without operation there is mortality of at least 20 per cent. With operation at the present time the mortality rate is near 5 per cent., and in hospitals under expert surgeons it is less than this.

When shall we operate? Every surgeon has answered this question differently at different stages of his experience. Whether he began as a conservative or an extremist he has changed, because he had a mortality rate which he hoped to lower by changing. I began very conservatively, operating only when a well-defined abscess was present. Under this practice the operative mortality was low, but the mortality

from the disease was high. Then came a period in which operations were performed by the calendar, or after careful selection. Under this practice the operative mortality was higher and the actual mortality considerably lower, but still too high. During the past few years the rule has been to operate as soon as possible after the diagnosis was made, and the actual mortality rate has been very much lower than that during either of the other periods. We abandoned the waiting plan because we have learned that while some patients will improve, many will die while we are waiting for a more favorable time for operation, and that no living man can tell what will happen in the next twenty-four hours in a case of acute appendicitis. After long experience with all plans we can conscientiously recommend operation as soon as the diagnosis is made, because it has been accompanied by the minimum mortality rate. We would not recommend this plan, however, for the unskilled operator or in the absence of hospital facilities.

In the Minnesota University Hospital we have had eighty-seven patients with acute appendicitis, all of whom have been operated on as soon as possible, with a mortality of but 3.4 per cent. This excludes all chronic cases and appendectomies made when the patient was being operated on for other conditions. Nineteen of them had extensive suppuration. It is of interest to note that all of our deaths occurred while we occupied the old frame building as a temporary hospital. The last forty-four cases have been operated in the new hospital with no mortality.

H. J. Paterson¹ reports a like experience. During the first period he rarely operated except in the presence of abscess, and never until the acute stage had passed, and the mortality was 16 per cent. During the second period each case was a law unto itself, and the mortality was 13 per cent. During the third period he operated as soon as possible in every case and in 95 cases had a mortality of only 5.2 per cent.

The term "operative mortality" means that the patient died in spite of an operation and not as a result of it. A few years ago a very common newspaper report was that someone had died from an operation for appendicitis. Even the laity have learned that the operation for appendicitis in competent hands is a very safe one, and that people die for want of an operation and not because of it. Christian Science is responsible for many more deaths from appendicitis than operations are. Many lives have been sacrificed and surgery has been brought into disrepute by surgeons who were striving to make a record. The record-maker is an unsafe man in surgery because he is very prone to give his record greater consideration than he does his patients. Every surgeon's actual mortality rate from appendicitis is made up of all deaths occurring among his patients whether he has operated or not.

Shall we always remove the appendix in acute appendicitis? To this question I answer, emphatically, No, because I have known of many instances in which the patient's life has been sacrificed through a determined effort to remove the appendix at all hazards. It should be remembered that the operation is performed to save the patient's life and not to remove the appendix. I have removed the appendix in fully 95 per cent. of cases during the past few years; but there have been a few cases, possibly one in twenty,

1. Paterson, H. J.: *Brit. Med. Jour.*, Oct. 5, 1912.

in which I deemed it safer to leave it. We believe that, at present, every experienced surgeon removes the appendix in the vast majority of cases, but that the best, that is, the safest, surgeons occasionally leave one. When the appendix is in evidence, it should always be removed, but when its removal necessitates the extensive breaking down of Nature's protection and the contamination of the general peritoneal cavity, it should be left for a later operation, when it can be removed with perfect safety. The leaving of the appendix in these exceptional cases with the established drainage is safer than its removal. The fact that leaving the appendix necessitates another operation is of no importance, because this is a matter of life and death and not of expediency. If it were the accepted practice to remove the appendix in every case, many lives would be sacrificed by inexperienced operators.

Should patients be operated on after an acute attack of appendicitis to avoid future attacks? The construction of the appendix is such that recovery is seldom if ever complete, and the fact that the first attack was a mild one gives no assurance that the next one will be. The interval operation is so free from danger, and later attacks of appendicitis are so often very dangerous, that we do not hesitate to advise the interval operation as a routine practice. In child-bearing women the operation should be insisted on.

How shall we treat appendicitis in pregnant women? Appendicitis in a pregnant woman is more than twice as dangerous as it is in a non-pregnant woman, and should be operated on at the earliest possible moment, for admitting that the operation and the accompanying anesthetic are attended with some danger, the disease without operation is infinitely more dangerous. The very great increase in danger during pregnancy is due to the facts, first, that two lives are in jeopardy, and, second, that the mother's condition renders her much more liable to grave complications. Abortion occurs in about 40 per cent. of these cases, which is always a very grave situation, and early operation is the best preventive of abortion. I believe that it is good practice to advise every woman who finds herself pregnant after a severe attack of appendicitis in which the appendix was not removed to have an operation as soon as she knows that she is pregnant.

The exact method of removing the appendix and of treating the stump is immaterial so long as it is skillfully done, for different surgeons employing different methods secure equally good results. In suppurative cases drainage is a very important matter, and is very often improperly carried out. It is a very grave mistake to plug the wound with gauze and depend on this plug for drainage, when it only prevents the escape of pus. My personal practice is never to use gauze for drainage except when it is surrounded by a rubber tube or rubber tissue, for it drains only serum and that for only a few hours, when its meshes are filled and it has lost its capillarity.

It is quite a common practice, at present, to place the patient in a sitting position to cause the pus to drain into the pelvis. I have not followed this practice, because it is based on mistaken theory, and it is an uncomfortable position for a feeble patient; and my patients have done just as well as those who were in a sitting position and have been much more comfortable. A few years hence this will be remembered as only a passing surgical fad. No matter what position a patient has been in before operation, with free

pus in the abdomen the pelvis will always be full when it is opened. It is very important to pump out the pelvis in every pus case. Large-sized soft rubber tubes should be passed to the bottom of the pelvis and into the flanks. It is not necessary that they should run down hill, for the intra-abdominal pressure will care for that.

Syndicate Building.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. MACLAREN AND MOORE

DR. ALBERT J. OCHSNER, Chicago: Some five years ago when Dr. MacLaren brought out the facts contained in the present paper I recalled several instances in which, undoubtedly, judging from the symptoms, patients whom I had observed should have had this additional treatment. Since that time I have encountered four cases in which this condition existed. In one of these there was an additional condition which might have resulted seriously to the patient had it not been discovered by accident. The patient had a greatly distended bladder so that there were two points of bulging, one point a little lower than the other, which made me suspicious that the bladder might be full and that this entire mass might not be due to the abscess. When the bladder was catheterized the abscess remained, but the upper swelling disappeared. In following the histories of these four cases I found that each patient had been carefully treated for some time by the use of cathartics. The shortest time of treatment was four or five days and the longest eleven days. I have never seen this condition present in any case in which the appendicitis had not been treated by cathartics. Many a surgeon with less skill than have the surgeons in this splendid new hospital referred to by Dr. Moore has a mortality in 100 successive cases of less than 3 per cent. by following a method of treatment of which I have spoken so often before this Association that the older members must know it by heart by this time. If in those cases in which the surgeon is doubtful, or feels that he cannot expect recovery, he inhibits peristalsis by washing out the stomach, performing gastric lavage and giving absolutely nothing, not even water by the mouth, feeding by the rectum, he will find that the mortality in this class of cases will be reduced to less than 2 per cent. Dr. Moore's plan of counting mortality is absolutely correct. Every patient with appendicitis who dies must be counted whether operated on or not. I believe in the Fowler position, and agree with what Dr. Moore said about operating during gestation. The reason the diagnosis is frequently not made is because in these cases the surgeon has not the intelligence or does not give the attention necessary to make a physical examination. Usually a patient who comes without having had an early diagnosis is one in whom the doctor took something for granted, not making a physical examination to begin with.

DR. J. M. T. FINNEY, Baltimore: Dr. Moore's paper was so sane and founded on such good surgery and pathology that it is difficult to disagree with him in any respect. There are one or two points, however, with which I disagree. He said the last word has not been spoken, nor will it be spoken until we have 100 per cent. recoveries. I agree with this statement. In appendicitis, in my judgment, the mortality is absolutely preventable. When a death occurs from appendicitis it is *prima facie* evidence that somebody has made a mistake. When pus is found in appendicitis, it is also *prima facie* evidence that somebody has blundered. It is not always the physician, nor is it the surgeon. It is not infrequently the patient or some officious member of the patient's family who interferes, and doesn't send for the doctor early enough. No case of appendicitis should progress so far as the formation of pus. I understood Dr. MacLaren to say that he had had no mortality whatever in any patient operated on except when pus was present. That is my experience. I think that it is the experience of a great many surgeons. If that is true, and the well-known and safe paths are followed in operating on these patients, I believe that mortality can be absolutely elimi-

nated in operations for appendicitis. This whole question, then, resolves itself into one of diagnosis. If the patient can be seen early enough, and if no mortality occurs in patients with appendicitis operated on except after the appendix has ruptured, it necessarily follows that 100 per cent. of recoveries will occur in patients operated on. That is a proposition which cannot be gainsaid in view of the facts in the case. If, then, it is a question of diagnosis, the thing we should devote our attention to for the time being is to improve our methods of diagnosis. There are ways in which that can be done. I cannot mention them all. Attention should be called to one or two points, however. If one has conscientiously examined his patient, as Dr. Uehsner says, if he has made use of every means at his disposal to make a diagnosis, and if he has failed to satisfy himself as to the existence or not of an appendicitis, if the condition of his patient is such as to make him believe that there is some more or less serious condition, it is the duty of the surgeon to offer, indeed, to insist on, operation. Make the diagnosis at the time of the operation if necessary, don't wait until the patient is as good as dead, and then attempt to do the impossible. That may seem to be an extremely radical position, but it can be backed up by the facts in the case, by statistics, by results, and that is what we are after. I call attention to the fact that appendicitis in children is a very different proposition from appendicitis in adults. I called attention to this fact in a paper some years ago, and reported a long list of cases coming under my observation in which all sorts of bizarre diagnoses had been made for appendicitis or the reverse. I have operated on a great many patients that I thought had appendicitis which did not so prove. I do not regret one operation. I am sorry to say I can look back on a goodly number of patients on whom I did not operate when I should and I had grave reason to regret it.

Dr. LINCOLN DAVIS, Boston: Much credit is due to Dr. Maclaren for his pioneer work in pointing out the advantages of rectal drainage in cases of appendix abscess. If we could operate on all cases of appendicitis at an early stage, there would be no need of this procedure. Unfortunately, in spite of much missionary work on the subject by surgeons, cases continue to come into our hospitals from the fourth to the tenth day of the disease, with large accumulations of pus. There is no doubt that there has been a great improvement in the mortality after operations for appendicitis in the last few years. This is due, I think, to three factors: (1) more efficient operation; the appendix is removed with less disturbance of the peritoneal cavity; (2) better drainage; the cigarette wick is certainly an advance over the old gauze pack; (3) more intelligent after-care. In the cases in which residual abscesses form after operation in spite of our best efforts to drain from above, there can be no question that rectal puncture is very definitely indicated. It is certainly safer to open such abscesses from below, rather than to poke down through the wound.

Preliminary rectal puncture, as advocated by Dr. Maclaren, has a more limited application, but still a very definite one in a small number of cases. I have not used it in just that way. I have drained two cases of appendix abscess by the rectum, without abdominal operation, with good results. The method is risky. The patient must be closely watched. There are nearly always two abscesses, one at the site of the appendix and the other in the pelvis. The drainage of one does not necessarily drain the other; therefore, after having drained the pelvic abscess, watch with the greatest care that there is no septic absorption from the original focus.

One point on which I do not fully agree with Dr. Moore is with regard to the value of Fowler's position; we use it extensively at the Massachusetts General Hospital. Postoperative rectal seepage is a life-saving procedure. Avoidance of violent catharsis is also an important matter. I have looked up all of my cases at the Massachusetts General Hospital, 249 in number. These were all acute, including general peritonitis as well. Every patient seen was operated on. Some of the cases were desperate ones. If they are sicker in the country farmhouses, they must be very sick indeed. In all but nine cases drainage was done. The appendix was removed

in all but thirteen cases, in which there was merely drainage of the abscess; in two cases by rectal puncture. There were thirteen deaths from all causes; mortality 5 per cent. plus. Secondary operations were done in ten cases; five were for drainage of residual abscesses; two by vaginal puncture, one by rectal puncture and two by incision in the flank.

THROMBOSIS AND EMBOLISM, THEIR SIGNIFICANCE AND CONSEQUENCES IN ABDOMINAL AND PELVIC SURGERY*

ANGUS McLEAN, M.D.

DETROIT

A condition which has been before the medical profession for many years, especially since the inception of modern surgery and modern surgical technic—a condition which is becoming more frequent with the ever-increasing number of abdominal and pelvic operations—a condition about which much has been written but concerning which little is known definitely, is the subject I wish to bring to the attention of this Section to-day. I refer to thrombosis and embolism.

The importance of this subject is at once apparent when we consider the great rôle played by thrombosis and embolism in raising the mortality in our surgical cases. Besides the mortality, the morbidity caused by these conditions is no small matter. Many are the cases of pulmonary, renal, and hepatic abscesses, not infrequent the cases of gangrene of extremities, necessitating amputation, that had their origin in thrombotic or embolic processes. Arteriosclerosis, a disease that in the course of time has been attributed to many different causes, is now looked on by many as originally due to embolic occlusions of many of the smaller vasa vasorum, is really the beginning of the arteriosclerosis. How does syphilis cause arteriosclerosis? The *Spirochaeta pallida*, circulating in the blood, become lodged in the smallest branches of the arteries. Their lodgment in the smallest ramifications of the vasa vasorum is really the beginning of the arteriosclerotic process. Likewise the other chronic low-grade infections often result in the same terminal process. These conditions do not, however, concern us now. In this paper I wish to consider, more especially, postoperative venous thrombosis and its probable resulting embolism.

Several etiologic factors are usually given as necessary for the formation of a thrombus: (1) trauma, especially injury to the endothelial lining; (2) stagnation or slowing of the blood-stream; (3) infection, and (4) chemical changes in the blood itself. Regarding these causes it is hardly necessary to say that not one is alone sufficient to produce a thrombus. When a thrombus does occur it is usually due to various combinations of these causes acting together. Again thrombosis often occurs, as, for instance, a femoral thrombosis that follows a surgically clean appendectomy, when, as far as we can ascertain, each one of these factors is wanting. We are therefore forced to look for some other etiologic factor in such cases. With the hope of finding some explanation for the thrombotic process in these cases, we† undertook some experiments on dogs.

* Read before the Section on Surgery at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

† Drs. R. C. Andries, W. D. Barrett and myself.

EXPERIMENTAL WORK

Experimentally, thrombosis is a difficult subject to work with, first, because of the difficulties that confront us in blood-vessel surgery generally and in the post-mortem findings in particular (as for instance locating the point of lodgment of an embolus) and, secondly, because the conditions under which thrombosis and embolus occur in the human being are difficult and practically impossible to imitate. At the outset we will say that we were unable to find any reason for their occurrence. We were, however, much impressed with the tremendous amount of injury a vein can withstand without the production of a thrombus at the site of the injury. Indeed, it is quite a difficult problem to produce a thrombus experimentally. In daily surgical work, all of us avoid injuring blood-vessels as much as possible. We always fear the possibility of causing a thrombus to develop.

In our experiments we noticed several interesting phenomena:

1. When a vein is ligated in continuity the blood in the vein will clot only on one side of the point of ligation, that is, the side from which the blood is coming.

2. In ligating a vein between two ligatures (say 2 inches apart) the blood between the ligatures clots very slowly and then only if the endothelial lining is injured, and if left for a week or more the contents of the ligated vein will have entirely disappeared, a fibrous cord-like structure alone remaining.

3. Simple crushing of a vein will not cause a clot at the point of crushing. The crushing can be repeated in forty-eight hours and a clot will not form at the site. Examination of the repeatedly crushed vein two weeks after the last crushing will show a thickening of all the coats of the vein due to an increased amount of fibrous tissue, the intima remaining as smooth and glistening as before.

4. Crushing of a vein with the subsequent introduction of a twenty-four-hour bouillon culture of staphylococci and again crushing the vein to grind (as it were) the staphylococci into the walls of the vein, will not produce a clot or thrombus at the site of the crushing and injection of the staphylococci.

5. The introduction of a sterile thread into the lumen of a vein, allowing about one half to three quarters of an inch to remain suspended inside of the vein, that is, oscillating in the blood-stream, failed to produce a clot or thrombus either at the point of the introduction of the thread or around the thread itself.

6. The introduction of a thread infected with *Staphylococcus albus* or *aureus* will in three or four days cause the formation of a thrombus at the point of the introduction of the infected thread. The thrombus becomes attached to the vein at the point where the infected thread enters. It will not entirely occlude the lumen of the vein; it will grow or enlarge in the direction of the blood-stream, remaining suspended at a single point. (See illustration.)

On examination of an induced thrombus of this kind it can readily be seen how easily such a thrombus could be torn from its small frail attachment, circulate in the blood-stream and become lodged somewhere in the pulmonary circulation and perhaps produce a fatal termination. In our experiments we were never fortunate enough to encounter such a termination. If such a thrombus did become detached in whole or in part, it lodged in a locality which had an abundance of collateral circulation and therefore passed unnoticed.

It is difficult to conceive a condition in a patient similar to the one in which we were able to produce a thrombus in the dog; but the difficulty found in producing a thrombus experimentally shows that there must be factors other than injury to the vessel, slowing of the blood-stream and infection that bring about a thrombotic process in human beings.

In necrosis, substances are produced which cause coagulation in the blood-serum which comes in contact with the necrotic tissue. Whether these substances first cause a hemolysis, a conglutination of the platelets and red corpuscles—a view usually held in regard to the method of thrombus formation—or whether these are substances akin to fibrinogen, and thus directly cause the coagulation of blood in the vessels, is not known. Is it perhaps possible that, when thrombosis occurs after a surgically clean operation, during the operation certain ligatures have been placed in such a way as entirely to cut off the blood-supply to certain areas, which subsequently become necrotic and liberate the substances necessary to complete the coagulation of blood in the surrounding vessels?

RELATION OF THROMBOSIS AND EMBOLISM TO OPERATION

In looking up the statistics we find that thrombosis and embolism follow operations for large pelvic tumors more frequently than any other operations. Of forty-eight reports of cases collected by Schenck¹ 58 per cent. followed operations for the removal of large pelvic tumors. Schenck² also shows that in 3,204 myoma operations from twelve different clinics namely, those of Goldman, Burnham, Wenczel, Duvergey, Hofmeir, Klein, Zurhelle, and Kelly, ninety-six, or 3 per cent., were followed by thrombosis. My own records of the last two years show that in 1310 laparotomies there were twenty-six cases, or about 1.9 per cent., that were followed by thrombosis or embolism. There were eight cases of fatal embolism, three cases of pulmonary embolus in which the patients recovered without further trouble, two cases of pulmonary embolus followed by lung abscess with recovery and one case of embolus of the liver followed by an hepatic abscess with recovery. Besides these cases of embolism there were twelve cases of femoral thrombosis all of which followed pelvic operations. Of the fourteen cases of embolism, eight, or 57 per cent., followed prostatectomies and hysterectomies. The striking thing in all cases of embolism and thrombosis in our series is that there was only one case of embolism with recovery and no cases at all of thrombosis that followed operations in the upper abdomen. This one case followed an operation for suppurative gall-bladder disease. In the cases that are most frequently followed by thrombosis and embolism there is always a certain amount of pressure exerted on surrounding structures. The circulation, especially the venous circulation, is retarded and extensive varicosities are quite common. There is also ample opportunity in these cases for remnants of tissue remaining, either in the form of devitalized pedicles or, as in the case of prostatectomy, shreds of connective tissue, which subsequently become necrotic and give off the substances necessary for the development of a thrombus.

Perhaps the most striking proof of the theory that necrotic tissue does cause thrombosis is presented in

1. Schenck: New York Med. Jour., Sept. 6, 1902.
2. Schenck: Tr. Am. Gynec. Soc., 1913.

those cases of pyosalpinx in which the whole fallopian tube is adherent and necrotic and can be removed entirely without ligating a single vessel. Similarly a necrotic appendix can be removed without ligating the appendiceal artery. Here ligation is not necessary because all the veins and arteries are already thrombosed from being in proximity to the necrotic tissue. The bleeding that does occur in these cases is simply an oozing from the newly formed capillaries that have developed in the adhesions.

We know that thrombosis is more apt to follow septic cases than aseptic ones. This can be readily explained. If the necrotic area is large it is difficult to imagine how it could remain free from infection even if it is an infection of such low virulence as to escape clinical detection. If therefore to the process of simple necrosis we add an infectious one, then we really have another factor for the production of a thrombus. We have an infectious condition, coincident with which there is always an inflammation and in the first stages of inflammation a slowing of the blood-stream is noticeable. If slowing of the blood-stream, inflammation and infection are at all contributory to the formation of a thrombus—and I believe they are—then the presence of all these factors, acting together with necrosis, ought to give us the greatest percentage of cases that are followed by thrombosis. This is exactly what happens clinically.

Thrombosis and its consequent embolism rarely occurs before the eighth day. The usual time is from the eighth to the twenty-first day. Recently a case came to my notice in which a fatal embolism occurred as late as two months after an operation for a uterine myoma. This is a rather slow process, but complete necrosis of the tissue, on which thrombosis to a great extent depends, is not a rapid process. It usually takes a week or ten days, about the length of time in which thrombosis usually appears. The thrombus that forms during this time may remain undisturbed almost indefinitely and again, at almost any time it may become dislodged wholly or in part, and give rise to an embolus. This explains why the time of appearance of a thrombus is earlier and more constant as compared to the late and quite inconstant appearance of an embolus.

The great majority of postoperative thromboses, except perhaps those which occur after mastoid or sinus disease—and these occur in the internal jugular vein—are found in the femoral or external iliac veins. In discussing the cause for the comparative frequency of femoral and iliac thrombosis, Clark³ came to the conclusion that it is due to the effect of traumatism exerted on the deep epigastric vein. The primary thrombosis originates in the deep epigastric vein and is slowly propagated along the line of that vessel until it reaches the external iliac vein, where it gives rise to a retrogressive thrombosis in the femoral vein. The long interval between the operation and the appearance of the femoral thrombosis suggests a slow process starting some distance away. It can be seen how a thrombus, once established in the deep epigastric vein, can be propagated to the femoral vein; but that simple trauma by retractors or the like should start a thrombotic process in the deep epigastric veins seems rather improbable, on the grounds that the most severe injury can be inflicted on veins without causing a thrombosis.

Can the formation of thrombosis and subsequent embolism be prevented? As long as we are unable to

say exactly on what factors thrombosis depends, so long shall we be unable to say definitely, whether or not we can prevent their formation. The probable causes as they present themselves to-day should of course be avoided. It is not possible to do this at all times. We cannot always avoid necrosis of tissue nor can we always avoid infections, for infections are often present before the case comes to the surgeon. In fact, they are very often the condition for which the patient seeks relief. Once a thrombus has formed, however, we can to a large extent avoid the occurrence of an embolus. The limb should be elevated to encourage the venous circulation, and kept warm, wrapped in cotton and surrounded with hot-water bags. Some advocate ligation of the vein proximal to the thrombus, but this we believe impractical in most cases and of doubtful benefit. Absolute rest must, however, be insisted on as a precaution against secondary embolism. This rest must be kept up until the clot has had a chance to become thoroughly organized, a process which will usually take from three to four weeks. If after the lapse of this time the patient is fortunate enough to have escaped the formation of a fatal pulmonary embolus from his thrombus, if he has escaped the long and tedious invalidism consequent on the lodgment of an embolus, either septic or aseptic, in his liver or elsewhere, his subjective suffering and discomfort is not at an end. Thayer⁴ examined a number of cases of postoperative venous thrombosis several years after their occurrence and found that, when the femoral and iliac veins were involved, the afflicted extremity was usually considerably and permanently enlarged. It presented varices often terminating in ulceration; in addition, there was marked weakness and cramps especially at night and on overexertion. Schenck² was able to gather the late histories (that is, four years old) of twenty-nine patients in the forty-eight cases in the Johns Hopkins series. Eight of them had symptoms for about four months and subsequently no trouble. Two had some difficulty in walking for about twelve months. Nineteen never fully recovered, being troubled with swelling and with more or less pain. On this basis he concludes that "it is fair to assume that about 65 per cent. of the patients never fully recover and that if complete restoration is to follow it will come before the end of the first year, by which time the collateral circulation is as completely established as it ever will be."

Some one has said that surgical morbidity does more to bring surgery into disrepute among the laity than surgical fatality. It is more lasting and it is continually and prominently before the people; whereas fatality is soon forgotten. If this is so, thrombosis and embolism more than any other condition should ever be in our minds as one of the possibilities that may put a practically indelible blot on even the most skilful surgery.

CONCLUSIONS

Endothelial damage, on which so much stress is usually laid, is not, *per se*, a cause of thrombosis.

Necrosis of tissue plays an important part in the production of thrombosis.

The main contributory causes are, probably, a low-grade infection, not of sufficient virulence to be noticed clinically, and slowing of the blood-stream.

STANDARDIZATION OF SURGERY

AN ATTACK ON THE PROBLEM *

ROBERT L. DICKINSON, M.D.

BROOKLYN

At one time the surgeon was almost the only skilled mechanical worker with a craft knowledge analyzed, recorded and disseminated. Now the man with the shovel and the apprentice bricklayer have outstripped him in technic, for in their activities essential motions, tools, and economy of effort have been studied and standardized and taught, while we who think ourselves open-minded scientists look askance at propositions to apply to ourselves measurements of action and efficiency and fatigue, record of errors, instructions in type, motion-training, submission to discipline and new adjustments of function and cooperation. The high average of equipment, dexterity, information, conscientious care and self-sacrificing humanity in operating-rooms, great and small, here and abroad, are matters which some years of planned travel and laborious note-taking heartily attest; but evidence is not lacking that advance is very irregular where it might be all along the line, and erratic rather than on any studied and unified plan.

Is it unfair to affirm that, on the whole, surgery is unstandardized? For example, what is standard nursing? Does Germany have an idea of American ward practice in this line? What is the standard treatment of chronic non-operative disabilities? Has America shown evidence of acquaintance with the outfit of nearly every large German hospital? What is high-grade care of the well-to-do, of the poor? Has London an inkling of the provision for private patients which is a feature of our hospitals, even in small towns? On the other hand, have we any understanding of their organized insurance relief among the lower classes? In surgical teaching how many countries have copied the one that gives nation-wide promotion for merit? Indeed, to make the point we do not have to select the larger issues; elementary every-day instances will do. For the simple abdominal incision where every factor may be worked out to standard, who has run a long course of tests? In stitching and tying have we settled what are the swiftest motions, as a peasant lace-maker has; or do we ever go into training for correct form? Yet piano-players, pugilists and golfers study these things. The diamond knows every player's batting average, the race-track publishes records, the government office rates men for accomplishment. But there is no hospital governing board which, when a vacancy occurs, or the day of annual reappointment comes round, can ask for the equivalent of a fielding average, or track performance, or rating for character of work done as applied to a visiting surgeon, a house surgeon or a nurse. A consensus of opinion made up of general impressions, of personal preference and prejudice decides. Who determines, anyway, whether a man is fit to operate at all? A doctor without surgical qualification may engage bed-room and operating room in one of the dozen private sanatoriums in any large city, or in the hospital of the little community, and proceed to do the gravest of operations. Until now the patient has had no way of knowing whether or not the doctor has had surgical

training. There is no graded standard at all. That the public does not want to be protected and would hinder standardization and legislate for "medical freedom" hardly lessens the duty to lay bare the facts and to present some plan for betterment. We may first, however, get some notions of what that plan might be and set them down. For we would not like to admit the extent of our ignorance, all the way from the specific requirements as to just what is the best material for a knife-blade, or the best way to sterilize it, up to the number and kind of hospitals needed in a particular type of community.

A beginning has been made. What has been done in Germany is ably recorded in Grober's book. Our hospital superintendents have one of the most practical and effective organizations in the country. A group of independent New York hospitals is working together in several matters, such as purchasing, issuing reports, checking up of the end-results of each surgeon's work, and promotion for merit rather than for seniority. Dr. W. G. Thompson of New York has shown the unnecessary number of miles of walking done by ward nurses because of poor room planning. Philadelphia has a Committee on Hospital Efficiency named by its County Medical Society to study the whole situation there with an efficiency engineer, Mr. Richard Waterman, as its secretary. Each of the fifty-five hospitals of the city has been invited to send to a conference an "efficiency committee" made up of the superintendent, a member of the lay governing board, and a member of the professional staff. There questions of uniform accounting, cooperative social service and studies of end-results are taken up. The reports are to be had from Dr. Edward Martin, 1506 Locust Street. The New York Board of Estimate has published pamphlets covering investigations by Mr. Henry Wright concerning Bellevue and Allied Hospitals, and has recast the organization. A beginning in the coordination and standardization of dispensary work has been made for the clinics of New York (and also of Brooklyn) by the Associated Out-Patient Clinics of the City of New York, with an office at 17 West Forty-Third Street. Groups of picked men of allied interests have found that at a cost of a couple of thousand dollars within the space of five years and by a very moderate alteration or enlargement of ordinary vacations they can see the best clinics of Europe and America at work and thus select the best experience. Surgical literature is abstracted in a way more nearly approaching symmetry and completeness than ever before in the joint American-German-French publication the *International Abstract of Surgery*. Furthermore, the degree of the American College of Surgeons will set a new standard here so that the public will understand what qualifications are fundamental. And, lastly, there is a demand for the standardization of hospitals that cannot fail to bring about far-reaching results.

A GENERAL PLAN

A scheme or proposal for standardization of hospitals and surgical technic and procedure and surgical outfits would be worthy of wide and concerted effort. How should it be attacked? I have tried to find out. Dr. Hornsby answers that the organization of hospital superintendents shows that they are fully awake to the need and have made great advances on the administrative side. The father of the newer studies of efficiency in industry, Dr. Frederick W. Taylor, who

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

has praised operative work as an example of well-planned procedure, writes me as follows:

In applying the principles of scientific management to hospitals I am sure there is an immense field . . . the best progress can be made if the work is done under the guidance of a man who has had practical experience in changing over from the old to the new type of management. . . . Unless the introduction of the new methods is made the special work of a man whose whole success depends on making

statement of every single item of outfit and action. A doctor should be assigned to the engineer who would do this, taking, if necessary, two years and making Century Dictionary-sized volumes.

As to the examination of the data, it is astonishing how just the laying bare of cold facts will be enough to reform and abolish no small proportion of the things that are wrong. Most institutions boggle at the proposal to make this kind of record. They are afraid of it. Most surgeons resent it, refuse it. But this is the way to better things—to chart every break in technic, stick it up, be public about it. And cure results.

In the matter of the planning department, ask any institution for its chart. It looks foolish. It hasn't any chart. [He showed the chart of a factory organization (Chart 1) and commented on it.] This chart may be modified easily to fit the health factory. The important matter is to divide and define the functions of the various individuals, particularly of the foremen. The questions in a factory or in a hospital are these: Who? When? Where? How? Upon what man does each one of these things depend for advice and control? There would have to be some alteration to fit this class of institution. For instance, there would be no speed boss. In place of a gang boss there would be a teacher. There would be a repair man. There would be an inspector, who would be a very important part of the organization. His work would be not so much investigation as prevention. Investigation is the finding out of the cause of trouble after it happens. Inspection is the keeping of everything up to the mark so that trouble does not happen. One might be said to be post mortem, the work of the pathologist. The other might be said to be preventive medicine. This man need not be a medical man. He is the checker up and is not the man who punishes or disciplines, for when he finds something going wrong, such as a nurse dropping gauze on the floor on her way to do a dressing, or making unsafe contacts, it is he who reports to the disciplinarian. All breaks, all technical errors of whatever kind are entered by him. If a surgeon makes a fault in technic it is entered without malice and without any other idea than that of checking up. Publicity about this list of errors is the great way of stopping trouble.

The disciplinarian is the man who decides all the questions bearing on faults made. His activity is not that of bouncer in general as the word suggests. A workman may

Chart 1.—Functions of scientific management, New England Butt Company, Providence, R. I., 1912.

quite rapid progress, the details are so great and the obstacles so many that even after a year or two of work, almost nothing seems to have been accomplished.

Then he gives warning that there are a multitude of fakers posing as efficiency engineers.

In Mr. Waterman's activities in Philadelphia, referred to above, an attack was made on the big problems in a basic fashion. That committee has not yet, I understand, reached the consideration of a plan of study of general surgical technic.

Mr. Frank Gilbreth, while condemning our methods rather fluently, has a program to suggest to us. He alone, as far as my questioning goes, has an answer to the query—yours and mine—What can I do—do now—to work out this thing in my own hospital, in my own line? This engineer has seen a considerable amount of operating in the United States and Canada and some in Europe. He has taken moving pictures of operations at New York Hospital, where he is consultant engineer, though he is, unhappily, too busy a man to be able to give much time to the institution. He asserts that hospitals are far behind factories in effective organization; that from 10 to 30 per cent. of precious ether moments could be saved, more especially in the period of preparation. "Surgeons," he says, "think not in terms of elementary motion, but in periods of elapsed time."

He outlined for me last February the way he would go about the study of our problems. He said:

The ideal way would be a demonstration hospital, but until one is started any institution could do these things: first, lay out a form for making a record; next, record the present practice in minutest detail; third, examine the data thus gained; fourth, organize a planning department, and last, adapt to your special needs the plan of carefully separated functions, with their functional foremen.

With regard to the study of detail, make stereoscopic pictures of everything. No detail is too small to write down. Trace the route of a pill from the manufacturer until it goes down the patient's throat. Make the most painstaking

Chart 2.—Functions of scientific management in hospitals (suggested by Gilbreth, drawn by Dickinson); *—professional control; †—executive control. Alternative: Omit "Professional Staff."

commit several faults. Under the old régime it was three times and out. Then he was bounced and a new man put in who was allowed to make four errors and then he was bounced and went off and got another job. Under the new way when the first man has made errors—one, two, three—he is every time gently but persistently corrected and correction continues until he ceases to make that particular error.

As far as possible all activities are charted in a peak and valley drawing. The peaks and valleys give us the clue to the high and low points of all our work and we proceed on these clear indications.

Be simple. Use few tools. Imagine yourself operating out under a tree. Hunt out the best experience, measure it, make it standard, write it down on an instruction card. Above all get your people thinking in terms of elementary motions.

The merit of these suggestions by Mr. Gilbreth lies herein, that he gives us something concrete to start on. The medical practitioner is still trying to work on the old one-doctor-one-patient scheme. American practice in surgical services has no clear plan. It works on what might be called a one-surgeon-all-function idea. In large hospitals the usual arrangement is this: The visiting surgeon is responsible, in his wards, while on a three months' tour of duty, for many varying and ill-defined activities. He plans, teaches, inspects, executes. His ideas may vary not inconsiderably from those of his predecessor or the man who follows him, but he has neither chart nor detailed written instructions to show others what these ideas are when his trimester begins. His force is yet to be drilled. By the time it leaves him it has begun to appreciate his needs and the group is working together. Members of the house staff are frequently jealous of and openly rebellious at assistance, however skilled, given at operations by qualified older assistant visiting surgeons. Except for the one in charge, the nurses are furnished to the operating-room to be trained and are removed as soon as effective. Checking up by the visiting surgeon is sporadic, never covering all detail in the whole of his service, never overlooking an entire day's activities. Supervision of a visiting surgeon is unknown. It is not too much to say that he actually accounts in details to no one, and presents no balance sheet.

In hospitals where a surgeon's service is continuous, some system prevails. Even here, however, there is no answer to the question as to how many hours a day or a week he is required to give to this unsalaried service. Nor is tenure of office fixed. Usually it is for life. The juniors serving long years never know what prospect there is of promotion. Nor can able men not connected with the hospital determine whether opportunity or experience may be obtained in service there, as they might should a limit of fifteen years be named for such service or a Codman plan of measuring men by their results be instituted to weed out incompetents.

PLANNING DEPARTMENT

While studies looking to wide changes in organization are under way, parts of the factory scheme might be adopted, such as a planning department, instruction, inspection. As to order of work and instruction cards, rules and regulations exist in every hospital—in the back of some dusty drawer. Wherein are many dead letters and few directions for details of every-day procedure. Ward routine is tradition; a newcomer alters it at will; an enema is given in three or four ways. A house officer starting on service gets directions as to his duties passed along by word of mouth. A head nurse imported to take charge of the operating-room rarely finds these things: a schedule of duties and of outfit; formulas; a list of stock instruments as agreed on by the staff, each article catalogued by its name and picture (in a place where tools are very various); diagrams of the instrument table for each operation or class of operations, and typewritten details of the procedure adopted as the standard average in this particular set of operating-rooms. Yet every employee can be provided with a schedule of duties and belongings. In any hospital, in each of the sections of

the planning department—order of work, instruction cards, time and cost, and discipline—the study of precedents and conditions could be taken up to-morrow and in time fairly complete schemes be submitted. This could be done by one man committees or members of the professional staff combined with the executive.

INSTRUCTION

The drill of the house surgeon cannot properly take place when explanation, question and pause are impossible—with blood spurting and seconds precious. The training in aseptic operative technic of the specialist on the eye, ear, nose and throat cannot be worked out by himself, yet there is no one whose duty it is to show him. These are but examples. High or low, every one of us needs better knowledge of standards and new methods. In no rationally planned way can this be brought about save to agree on standard and to delegate the general teaching and leveling up to some qualified individual or individuals. In the training-school we are used to this daily instruction. On the professional side it is haphazard.

INSPECTION

It is not easy to adjust our point of view to the idea that the actions of all of us are to be checked up and compared with certain standards while our breaks are calmly tallied and bulletined and our results are openly scheduled. As it is at present a visiting or associate surgeon may be a striking success in diagnosis or technic but in other points like after-care or progress or humanity be grievously defective. Who may tell how the balance is to be struck under present methods?

SUMMARY

Pending the working out of a comprehensive plan we have outlined the progress already made in the direction of standards and coordination, and pointed out the way an individual surgeon or service may begin to try out certain of the advanced methods adopted in the management of industries. Some of these are new adjustments of "function" (responsibilities and duties) clarified, charted, defined; regular instruction, such as drill in technic and manual dexterity and correct form; practice in team work; the printing on instruction cards of the best standard practice covering all ordinary acts and activities; constant inspection by one delegated to this duty; record of successes and errors like a ball-player's fielding average or a government office tally of character of work done; promotion by rating, and finally, a series of studies, undertaken as in the other mechanical crafts, by measurement of motion, speed, fatigue and efficiency.

168 Clinton Street.

The Habit of Observation and Medical Education.—The one constant characteristic of all those great men who have done so much for our science is their power of accurate observation and logical deduction. . . . This habit of accurate observation is one which it is not easy to acquire. . . . But in acquiring this habit you must not be conscious of doing so, for this "self-training, self-suspicion and self-discipline" consists in absolute concentration on the work which you are doing at the moment, the cultivation of a desire for knowledge for the sake of knowledge alone, and the putting behind you of all desire to generalize or theorize without a thorough sifting of the facts. You must not constantly be looking for the practical application of the knowledge you acquire. Be content to acquire it, resting assured that the practical application will come in some form later. —B. P. Watson, *Canadian Med. Assn. Jour.*, June, 1914.

KRAEPELIN'S CONCEPTION OF PARAPHRENIA *

MORRIS J. KARPAS, M.D.

Assistant Resident Alienist, Psychopathic Department, Bellevue Hospital
NEW YORK

INTRODUCTION

The subject of paranoia forms one of the most important chapters in the history and evolution of psychiatry. Esquirol, Lasèque, Hoffman, Snell, Westphal, Mendel, Kraepelin and a score of others helped to lay the foundation of the paranoia concept. Esquirol attempted to bring a group of cases of paranoiac conditions under the heading monomania; in 1852 Lasèque described a disease picture under the name of *delire de persecution* which was later named after him by his countrymen as *delire de Lasèque*. In 1862 and 1865 Hoffman and Snell independently of each other gave careful attention to this subject. It was not until 1878, however, that Westphal made paranoia felt and recognized in Germany; he termed it *Verücktheit* and Mendel invented the term "paranoia."

Since then the subject of paranoia has undergone many stages of transformation and variation. At one time the whole subject was in a state of confusion partly because mental diseases were incorrectly classified, partly because of deficient knowledge of the anatomy and psychology of insanity and partly due to the fact that too much stress was laid either on the symptomatologic display or etiologic foundation. It is needless to state that very little attention was paid to the disease process in all its phases, particularly in relation to the constructive development of the symptomatic picture and type of personality.

It should be borne in mind that Kraepelin in 1892 had already emphasized the fact that the paranoia group should not be looked on from the point of view of isolated symptoms, but that the whole clinical picture, including the etiology, course, duration and termination, should be considered. It was through the efforts of Kraepelin's genius and painstaking investigations that the paranoia subject assumed a more lucid scientific turn, and indeed, while the whole solution of the problem has not been completed, nevertheless our conception of paranoiac reaction types has taken a more promising view.

In the present state of our knowledge, we differentiate two large classes of paranoiac reaction types, one a paranoid symptom complex, which occurs in various toxic conditions and which may also form a part but not the dominant symptom of other types of mental disorders, for instance, a paranoid symptom may manifest itself in manic depressive insanity, hysterical psychosis, senile dementia, arteriosclerotic insanity, etc. In the other instance, the disease pictures are dominated by a paranoid symptom complex which presents various clinical manifestations in their course, such as in dementia praecox, paranoid form, paranoia, querulous paranoia and paraphrenia. The last is the subject-matter of this thesis.

GENERAL CONSIDERATIONS OF PARAPHRENIA¹

Paraphrenia forms a subgroup of endogenous dementia and in the clinical picture delusional ideas are the predominating symptoms. In some respects

it may simulate dementia praecox, but there is no characteristic disturbance of emotions and volition to such an extent as to bring about disintegration of personality. Abnormality of emotional activity, however, may be noted, but striking apathy and indifference as seen in dementia praecox are lacking, and furthermore the general conduct is influenced by abnormal thought processes and not by volitional disturbances. The etiology of paraphrenia is not definitely known and there is no specific type of heredity. It occurs in both sexes, except that the expansive form is limited to women only. The characteristic type of personality is not determined. The development is gradual; the course is progressive and the disease usually terminates in a state of psychic enfeeblement but without evidences of disintegration of personality and striking traits of emotional and volitional deterioration. Paraphrenia may be divided into four large forms: (1) systematized, (2) expansive, (3) confabulatory, and (4) fantastic.

THE TYPES OF PARAPHRENIA

1. Paraphrenia systematica is characterized by gradual development of progressive persecutory delusions and grandiose ideas, which appear in the latter part of the disease. As a rule the personality remains intact.

The onset of the disease is usually gradual—a slowly progressive change of disposition is noticed. The patient becomes quiet, reserved and dreamy. He grows secretive, seclusive and suspicious. His general conduct is odd, and occasionally he gives expression to irrational utterances. At times sensitiveness and irritability are observed. Under the least provocation he may manifest violent outbreaks and show animosity toward some persons of his environment, particularly against his relations. Not infrequently ideas of jealousy are in evidence.

In course of years the delusions of persecution become more and more marked. The patient imagines that he is being watched and followed; he expresses ideas of reference and misinterprets occurrences. He feels that people talk about him wherever he goes and thinks that detectives are sent to watch him. In fact, he feels that he is under constant observation of the police. He notices people making funny grimaces and gestures and he is the subject of trickery. In female patients sexual ideas are prominent. Likewise ideas of poisoning and delusions of being tortured are observed.

After years' duration of this painful state of suspiciousness, uncertainty and tension, actual hallucinations, particularly in the auditory field, make their appearance. The content of hallucinations varies, and inspirations and the like may occur. A feeling of influence is noted. The patient imagines he is subject to hypnotism which is employed to determine the working of his thoughts; and he believes that he is under the influence of other people's minds.

Visual, olfactory and haptic hallucinations may become manifest; women particularly experience sensations in the genital region and speak of mental sexual intercourse. Not infrequently ideas of hypnotic, magnetic and electrical influences are associated with these abnormal somatic sensations.

When in the course of many years persecutory delusions gradually and progressively become developed, ideas of grandeur set in. The latter are very rarely noticeable in the early inception of the disease or thereafter. In some instances erotic rela-

1. Kraepelin: *Psychiatric*, Ed. 8, 1913, pp. 973-1022.

tions to great personages are maintained. Delusions of a religious coloring with a marked grandiose trend are seen in a small number of patients. The relationship between the delusions of persecution and the ideas of grandeur is the same as in other psychoses.

The underlying mood is mostly one of depression and apprehensiveness; the patient gradually becomes more and more suspicious, hostile and threatening. Later when delusions of grandeur develop the patient becomes self-conscious, haughty and sneering. He is seclusive and secretive, however; at times he is abrupt and inaccessible and then again he exhibits considerable politeness and is quite approachable.

The patient remains clearly oriented, and the perceptive faculty shows no impairment. Memory and retention are likewise unaffected. Falsification of memory is noted, and the patient maintains that he is persecuted since childhood and indulges in other numerous retrospective misinterpreted reminiscences.

As a rule the patient exhibits no insight into this condition, although in the early beginning of the disease he may appreciate that his situation is due to hallucinations, voices telling him that he is mentally sick, etc.

The conduct is usually influenced by the delusional content, although for some years mental adjustment may not be interrupted. Soon the disease betrays itself, however, and the patient exhibits difficulty of adapting himself to his environment. The capacity for work is retained—in fact some patients may hold responsible positions for years.

The course of this disease is insidious and gradually progressive. The condition may show some variation but to a limited degree. The disease terminates in a state of psychic infirmity with persistent delusional ideas and hallucinations but without disturbance of volition or dulling of emotions. Although the disease may last over twenty or thirty years, yet the personality remains intact.

The underlying etiology is obscure. A specific form of heredity cannot be determined. No known cause can be ascribed. A definite type of personality is not recognized by Kraepelin, though he admits that some of his patients manifested peculiar traits before the development of the psychosis. Some of his patients were sensitive, overreligious, inclined to be despondent and others were of a malicious and sadistic nature.

This form of paraphrenia occurs in both sexes: in Kraepelin's cases 60 per cent. were men and 40 per cent. women. More than 50 per cent. of cases occurred between the ages of 30 and 40; 20 per cent. of the cases developed between 40 and 50, and 25 per cent. below the age of 25 and above 50.

2. *Expansive form.* In this form of paraphrenia exalted ideas of grandeur with a preponderant elevated mood and mild excitement constitute the characteristic features of the disease picture.

The psychosis usually develops gradually, but at times a subacute onset may be observed. In 50 per cent. of Kraepelin's cases the grandiose ideas were of an erotic content. In another series of cases the delusions take a religious trend. In other instances ideas of wealth are prominent.

Almost always hallucinations make their appearance. The patients have numerous dream-like visions which as a rule are of a religious and erotic coloring and quite often they may be accompanied by auditory hallucinations; the latter, however, may also occur independently. Here illusions may play some rôle.

Hand in hand with the grandiose ideas, delusions of persecution may form a part of the clinical picture, which are not as prominent as in the other forms of paraphrenia.

The memory, orientation and perceptive faculty are not affected. However, falsification of memory not infrequently is observed.

The underlying mood is one of exaltation; the patients are self-conscious, haughty and quite boisterous. They are given to jesting and wit. At times they may become irritable, overbearing, arrogant and suspicious. Occasionally outbreaks of excitement occur.

The conduct is controlled by the morbid ideas and as a rule insight is lacking.

In the further course of the disease, the clinical picture slowly undergoes some changes. In general the patient remains clear and well-behaved; however, they adhere to their delusions which become somewhat absurd and rambling. Aside from faulty judgment there is a certain degree of dissociation, superficiality of emotional activity and weakness of will-power, but no true dementia. The personality is not distorted.

It is interesting to note that Kraepelin's cases were all women. Three-fourths of them developed between the ages of 35 and 50. In one of his cases the psychosis appeared at the age of 64, without, however, showing signs of senile dementia. Marked hereditary taint or external cause could not be determined. While no definite type of personality could be elicited, yet many of his patients manifested some peculiar traits prior to the development of the malady.

This form of paraphrenia may be mistaken for chronic mania and, indeed, some of these cases Kraepelin had previously included in the manic-depressive group. It is important to bear in mind that in the expansive form of paraphrenia, psychic enfeeblement invariably occurs; the excitement is relatively mild and without a history of previous attacks which would aid one in making a differentiation from manic depressive insanity.

3. *Confabulatory form.* In this form of paraphrenia, falsification of memory is the prominent feature in the clinical picture.

Only a limited number of cases came under Kraepelin's observation.

The development of the disease is characterized by a change in the patient's disposition. He becomes quiet; seclusive, irritable, he indulges in subtle inquiries and gradually commences to relate fantastic experiences which express themselves in delusions of persecution and ideas of reference, hallucinations and delusions of grandeur.

The delusions of persecution go back to their early childhood. For instance, the patient maintains that he was mistreated in school; that he was ridiculed by his relatives; that he was driven to masturbation; that his mother tried to poison him with an apple, and that he met people who wished to kill him; and he expresses other peculiar ideas.

The delusions of grandeur are likewise of fantastic nature and colored by falsification of memory. The patient believes himself to be a descendant from the royal family, or that he is the natural son of the king, and the like. He affirms that in school the teacher regarded him as the prince; that he was selected for the kaiser but he was too young. In such a way the patient may relate numerous fantastic grandiose adventures in the form of personal experi-

ences. Furthermore, he is capable of misinterpreting and distorting past occurrences.

The content of falsification of memory does not always limit itself to the peculiar persecutory and grandiose ideas, but it may take a retrospective trend and also find expression in the experiences the patient encounters in his daily life.

Quite often falsification of memory is associated with his immediate environment—for instance, he maintains that everything is familiar to him; imagines that he was formerly in the hospital; that nurses and patients are his old acquaintances, etc.

Sensorium is not perturbed; the patient is collected and takes cognizance of what transpires about him; gives clear and connected answers and is well-behaved. So long as his delusions do not dominate his entire personality he is clear as to his whereabouts and has good grasp on his environment.

The mood is elevated and exalted. However, transitory states of anxiety and irritability are observed. Most of the patients are loquacious and show tendency to play of words at times.

The course of the disease is progressive. "Mostly the exultant manifestations of the falsifications of memory may form a relatively short stage of the disease although the delusional fabrications continue for a longer period of time, but recurs and may possibly become more elaborated."

As time goes on the delusions become more senseless and rambling; the patient grows irritable, surly or indifferent, and finally a state of psychic enfeeblement is fully developed. As to the ultimate outcome of the clinical picture, Kraepelin cannot definitely state. Some of his cases lasted more than a decade.

This form of paraphrenia is not frequent, and Kraepelin has seen only a dozen such cases for the past thirty-five years. The two sexes may be equally affected. The disease develops between the ages of 20 and 50. No known cause could be assigned. In most cases the patient indulged in gloomy meditations long before the development of the psychosis.

4. Paraphrenia phantastica is dominated by exalted productions of marked fantastic, loosely connected, changeable delusional ideas.

Quite frequently the disease is ushered in with a depression. The patient is low spirited, dejected, anxious and expresses suicidal ideas.

Delusions of persecution gradually make their appearance. The patient imagines that he is the object of persecution, that he is under constant observation and that people talk about him. He expresses other peculiar ideas—thinks that he is to be punished for murder, larceny, etc.; imagines that he finds feces, sputum and human blood in food. Everything is drenched with arsenic, phosphorus and chloroform. Neighbors enter his room in his absence and steal clothes from him and destroy things.

Hallucinations of hearing also constitute a part of the picture. The underlying content may be threatening, persecutory, commanding, erotic or grandiose. Visual hallucinations may also occur.

Ordinary sensibility occupies an important position in the clinical picture, and on this, delusions of personal influence (*Wahn der persönlichen Beeinflussung*) are founded. The patient complains of all kinds of pains and other somatic sensations in the limbs, head and chest. He also speaks of perceiving electric shocks and receiving hypodermic injections. He imagines that his serum is electrified; that his organs

are torn out; that his voice is changed; that his whole body is transformed; that memory and his thoughts are controlled by spiritual devices, witchcraft, etc. Ideas of being hypnotized and sexual delusions are also present. Marked somatopsychic delusions of a fantastic and sexual undercurrent are often encountered—for instance, he feels that he sees men in his body—that the kaiser is in his body for the purpose of being rescued; that his father sits in his right leg; that a princess sits on his penis; that a female genital organ developed on his eye; that he consists of thirteen persons and that eight women are within him; and he expresses numerous other fantastic ideas.

In addition numerous fabrications of a fantastic nature play a rôle in the clinical picture.

Many of these delusions become cloaked in the form of falsification of memory with an underlying fantastic trend. He maintains that as a child he was robbed—that he was killed several times; that he was Christ, Eve, Moses, Alexander the Great, etc.; that he created the first people; that he studied medicine for 200 years and then again he reigned for 200 years; when he was 7 years old he ruled the world. He indulges in numerous other fabrications, etc.

The mood is slightly elevated or one of indifference. At times he may become gloomy and give vent to violent outbreaks of excitement. Irritability may also be observed, especially during longer interviews.

It is interesting to note that the patient is able to give an account of himself and answers questions to the point. His manner, however, is affected and grimaces are frequently observed. He also gives expression to senseless rhyming and play of words.

The course of the disease is progressive and gradually the utterances become confused and absurd. Neologism, very odd conduct and other eccentricities become quite marked. Emotional responses grow duller and transitory periods of violent outbreaks and irritability are of frequent occurrence. Nevertheless, many of the patients are capable of doing their work without interruption.

The rapidity of the dementia varies. In some cases it is noticeable soon after the appearance of the psychosis, within four or five years. Kraepelin knows of cases in which, aside from fantastic delusions of a peculiar confusion, he was able to demonstrate no higher grade of intellectual deterioration.

From 60 to 70 per cent. of his patients were of the male sex; on one-half of his cases the disease developed between the ages of 30 and 40, and in one-fourth below 30 and in the rest above 40. Some of his patients were of good mental endowment and of a vivacious disposition, but were inclined to indulge in subtle fancies. Others were weak-minded, stubborn and wayward. It is also interesting to note that many of his patients showed criminal propensities.

CONCLUSION

It must be admitted that the splitting up of a large heterogeneous group into subgroups with the object of restricting the disease picture to definite clinical types implies a marked advance in objective psychiatric nosology. Hence the paraphrenia group is such a welcome addition to the modern classification of mental disorders. One must bear in mind in many instances a well-defined line of demarcation between dementia praecox and paraphrenia is quite often very difficult to make; especially is this true of the confabulatory and fantastic forms. It is important to emphasize that in

the psychopathology of dementia praecox, emotional and volitional deterioration and distortion of personality stand out quite prominently, but they are only objective landmarks to aid one in establishing such differentiations. Kraepelin lays little or no stress on the type of personality in paraphrenia or other forms of psychosis, which is so much emphasized in American psychiatry, chiefly due to the painstaking efforts of Meyer and Hoch. Should it be possible to outline a characteristic type of personality and the underlying psychologic mechanisms of a paraphrenic symptom complex our knowledge of this important group would be greatly enriched.

One cannot dismiss the subject without saying a word or two regarding the differential diagnosis between paraphrenia systematica and true paranoia. It would be recalled that the former is considered a disease process inasmuch as it has a definite onset course and termination. According to Kraepelin's² present conception, however, paranoia is not a disease process, but he looks on it as a peculiar psychopathic personality—"psychic malformation." The root of this condition is sought in the peculiar paranoid anlage of the patient. The development of delusions is very slow and progressive which evolved from the personality, which at no time shows any distortion. In the clinical picture, delusions of grandeur are the foreground which result from inner conflicts and struggles, and evidently represent a fulfilment of an ungratified wish or dream.

ABSTRACT OF DISCUSSION

DR. H. DOUGLAS SINGER, Hospital, Ill.: I have studied this conception of paraphrenia by Kraepelin a good deal. I think it represents merely a way of getting out of a good many difficulties in which the system of Kraepelin's classification lands one. You will find that this particular group is composed of a number of cases which did not fit in very well in his previous classifications. Some of them represent cases which he previously classed as manic-depressive insanity with a paranoid trend. He admitted at that time that he did not know just where to place them. These have now been transferred to this group without much more justification than from that point of view. His paraphrenia phantastica represents what he called dementia paranoides in the older dementia praecox group. And this group, taken all together, really represents mental disease pictures which he has found difficult to class in any other way. He has simply put them in a separate class and attempted thereby to outline more clearly the other groups which have already been so widely accepted. I feel that all the multiplication and names and subtypes which we get in this way is a disadvantage rather than an advantage, especially when it comes to speaking of differential diagnosis between the different types. With the general conception of mental disorders which I have, in common with a good many others, I can but feel that these paraphrenic disorders again are simply individual modes of meeting situations. That in these people, who certainly present a very peculiar way of doing things, one sees a peculiar kind of personality. As Dr. Karpas says, we unquestionably will learn much more when we recognize the peculiar individual make-up which leads to these reactions. I do not feel that this represents a great advance. It is simply shelving the question of what these conditions really are and trying to maintain and define more clearly a dementia praecox disease by putting aside those cases which cannot be so clearly grouped under this conception.

DR. L. B. PILSBURY, Lincoln, Neb.: I feel as Dr. Singer does, that the newer classification has fallen into some of the faults of the old; that is, it is, as time passes, becoming more

complicated, less simple in every way, less clearly defined; in fact it is becoming top-heavy. The attempt to define more clearly is what is really bringing about this complicated situation, to be sure, but the result has been simply to befog the issue rather than to clear it up.

DR. MORRIS J. KARPAS, New York: It is true that our classification of mental disorders is incomplete and imperfect; nevertheless, an objective nosologic classification is desirable, especially from the point of view of prognostic outlook. By understanding the type of personality and the underlying psychologic mechanisms of the various psychotic manifestations, much can be accomplished toward our knowledge of diagnostic groupings. It is admitted both by the synthetic and analytic psychiatrist that classification of psychoses is indispensable for the progress of psychiatry.

THE RELATION OF PATHOLOGIC CONDITIONS IN THE NOSE AND THROAT TO THE ORIGIN AND TREATMENT OF HYPERTHYROIDISM *

S. P. BEEBE, PH.D., M.D.

NEW YORK

The thyroid gland prepares an internal secretion which is not limited in its action to a single mechanism, as is the case with secretin. There is much evidence to support the belief that it acts on a wide range of tissues. Prominent among the theories of its function is that of detoxication, but the mechanism of its action in this respect is not well understood. The older theories of Notkin and Blum are no longer acceptable. The metabolic activity of the tissues in a thyroidectomized animal is below *par*. There is a lowered oxygen absorption, greater tolerance for carbohydrate, a lower body temperature and a diminished activity of both physical and mental processes. The whole picture is changed by the administration of thyroid extract. Poisonous substances which might seriously affect an animal in the abnormal condition following thyroidectomy may not be so dangerous to a normal animal or to one receiving thyroid extract; not because of a direct antagonism or neutralization of the toxin by thyroid secretion, but rather because the inactive tissues of the thyroidectomized animal are less able to protect themselves.

The experiments of Perrin and Jeandelize show that a thyroidectomized animal is more susceptible to bichloride poisoning than normal animals. Frugoni and Grixoni assert that animals with experimental tuberculosis are favorably influenced by continued administration of thyroid extract. These results are to some degree confirmed by the experiments of Marbé, who found that the phagocytic function of the leukocytes and the opsonic index of the blood are distinctly lowered by thyroid removal and stimulated by thyroid administration. Numerous clinical reports show the common belief in the diminished resistance of hypothyroid subjects to the common infections, and beneficial action of thyroid administration in such cases. Sajous has advanced the hypothesis that the mechanism of the defense against infections depends to a large degree on thyroid function.

The most complete experiments showing the anti-toxic value of thyroid feeding are those of Hunt, who has found that white mice are protected from acetoni-

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

tril poisoning by thyroid administration and that there is a close quantitative relationship between the amount of thyroid given and the amount of poison to which it affords protection. The protection to toxic substances evidenced by these experiments is not a universal phenomenon, however, for other animals such as rats and guinea-pigs are rendered more susceptible to acetoneitril by thyroid administration, and mice which are protected to acetoneitril poisoning are rendered more susceptible to morphin. Such observations indicate a marked alteration in the metabolic processes of the animal rather than a mechanism of protection.

The relation of thyroid disease to previous infections has been noted clinically by many observers. In this connection it is well to remember that thyroid disturbances occur most frequently in persons of a thymicolymphatic constitution, and it is these individuals who are most susceptible to infections. The terminal event in hyperthyroid patients is not infrequently an infection which has begun in the tonsil, and I have not seen a necropsy in these instances which did not disclose the characteristic pathology of status lymphaticus. Its most common occurrence in women and its relation to the functions of the sex-glands, such as puberty, menstruation, pregnancy and lactation, are worthy of note.

A large percentage of patients with exophthalmic goiter have enlarged tonsils and adenoids. They give a history of repeated attacks of acute tonsillitis. Not infrequently one or more of the accessory sinuses are or have been infected. It is not uncommon to date the beginning of the thyroid enlargement from a particularly severe attack of tonsillar infection.

Infections in the nose and throat are undoubtedly the most common to which the human family is subject, and with that fact in mind one so disposed might build an hypothesis relating many of our ills to that forerunner. And such a conclusion would in many instances be justified for the tonsil is one of the most important ports of entry we have for infections; but in this case the resultant condition is a hyperactivity of a gland of internal secretion and not a continued infection. It is obviously more difficult to explain such a result than to trace the connection between an acute tonsillitis and a septicemia or an infected joint. An observation of much interest in this connection has been made by Halsted. In 1888 he removed a large part of the thyroid gland from normal dogs and found that the portion remaining became hyperplastic. These experiments have been widely accepted and quoted to prove a capacity for compensatory thyroid hypertrophy, but twenty-five years later, in 1913, he repeated the experiments and found that he could no longer get the same results. In the first experiments the animals' wounds were invariably infected, while in 1913 he employed careful aseptic methods and obtained primary union. Halsted does not draw the conclusion that the wound infection causes the hyperplasia, but he recognizes that such may be the case. The relation between infection and thyroid hyperplasia has further support in the experiments of de Quervain, who found that the injection of bacterial toxins caused a marked hyperplasia similar to that produced by Bircher in rats by giving them water from goitrous wells.

The theory of the origin of thyroid hyperplasia from a specific infection has been recently reviewed and developed by Gaylord in his report on carcinoma of the thyroid in salinoid fishes. In the course of

this work he studied the effects on the thyroid of rats and dogs produced by mixing with their food sediment obtained from the ponds inhabited by the goitrous fish. Such a diet produced quite remarkable thyroid hyperplasia in some of these animals; more striking, in fact, than that produced by McCarrison, who produced thyroid enlargement in goats by giving them water contaminated with the feces of goitrous men.

Infection does not in a large percentage of cases produce such an enlargement of the thyroid gland that it would be recognized as a goiter, and it may be that the thyroid does not react in this manner except in those who are not quite normal in respect to the balance of their glands of internal secretion. If the thyroid secretion is an important element in the defense against infections, it is not impossible that it is stimulated to overactivity when occasion demands, and if the stimulus be often repeated it may produce changes which we recognize as pathologic. Through the repeated stimulus to over-activity, the gland has become hypertrophied, and its heightened function continues long beyond the stimulus which called it forth. Certain experiments which I have published show beyond reasonable doubt that the discharge of iodine from the thyroid is to some degree under nerve control, but this fact does not argue against other influences working to the same end. The gastric secretion is under two influences, one nervous and the other chemical, and it is by no means unusual to find patients with a hyperactivity of the glands secreting the hydrochloric acid of the gastric juice.

Clinically there is an important relation between the infections in the nose and throat and hyperthyroidism. In patients between the ages of 16 and 24, from 35 to 40 per cent. give a history of repeated attacks of acute tonsillitis, and many of them have a chronic pharyngitis and rhinitis with enlarged tonsils and adenoids. Not infrequently one or more of the accessory sinuses is infected. It is by no means a rare thing to find that a rapid enlargement of the thyroid with characteristic symptoms of overactivity has followed immediately after a particularly severe tonsillar infection. Such patients bear these infections badly. Their convalescence is slow and each attack is accompanied by severe prostrations quite out of proportion to the seeming severity of the infection. It has been my observation that the leukocytosis accompanying these infections is lower than usually found in similar conditions in non-goitrous patients, and, although they may have the local condition characteristic of quinsy, they do not usually form an abscess which gives free pus when opened. Hyperthyroid patients often show a marked leukopenia with a relative lymphocytosis indicating some influence on the blood-picture, and this influence is evidently operative when the organism is subjected to infection.

There is no complicating factor in exophthalmic goiter which is more troublesome or more dangerous to the patient than the tonsil infections to which they are subject. Every effort should be made to prevent them. When the patient's general condition will permit, the tonsils should be enucleated and the adenoids removed. But such an operation should not be done on a patient suffering from an active thyroid intoxication without appreciation that such patients do not stand operation of any sort well, and all precaution should be taken to prevent shock from the ordeal. The methods followed by Crile in stealing the thyroid

apply quite as forcibly to operative procedure of every sort on these patients. It has not infrequently happened that the surgeon has been surprised by the unusual reaction following tonsillectomy and has found on closer examination that his patient had an enlarged thyroid with most of the symptoms of hyperthyroidism. Such an observation should precede and not follow the operation. The relief which follows the elimination of infection, whether in the sinuses, the nasopharynx or tonsil, is usually so prompt and effective that one has little doubt as to its causal relation to the overactive thyroid, and it becomes at times more important to attend to the infected areas than to attempt direct action on the thyroid. By so doing many patients will be permitted to retain their glands for a useful function.

Every young patient with an enlarged thyroid should have a careful examination of the nose and throat, and the converse is equally true. Between the ages of 12 and 20 is the beginning point of most thyroid enlargements, and it has been my observation that a combination of enlarged chronically infected tonsils and adenoids, gastro-intestinal disorders accompanied by constipation, and an enlarged thyroid with mild nervous and heart symptoms is the beginning of a condition which usually does not attract much attention unless the patient (and these individuals are nearly always young women) is annoyed by the cosmetic defect in the neck. This is the physical foundation to which such girls bring the exacting demands of school, college and social life, and under its strain a large percentage of them sooner or later fall as victims. Hyperthyroidism can be checked in such patients before any serious damage is done if the beginning is recognized. It is unfortunate that the facility with which the thyroid gland can be removed has led to many needless operations in the type of patient described.

The beginning of thyroid disease should receive more attention. Too frequently it is overlooked, and when discovered is taken lightly except in the face of quite disturbing symptoms. The progress of preventive medicine will ultimately lead to the discovery of most of these beginning cases at a time when they are easily curable with preservation of the integrity of the thyroid. Medical inspection in school and college should accomplish a great deal more in this respect than it now does.

414 East Twenty-Sixth Street.

ABSTRACT OF DISCUSSION

DR. CHARLES G. JENNINGS, Detroit: One word concerning the question of diagnosis; what symptoms will put the examiner on the track of thyroid toxemia? So far as my experience goes, there are two symptoms of the greatest value, which are easily elicited by the usual examination. They are the debility and the tremor. Both may be mild but are almost uniformly present. The question of therapeutics is largely hygienic. Rest is perhaps the most important. Girls in early adolescence, in boarding schools particularly, suffer from a mild type of the trouble and they must be given rest; social, intellectual and physical rest. The wear and tear of social functions often bring about this condition. As to medicinal treatment, my experience is that in these cases, in spite of the fact that they are cases of hyperthyroidism, the patients do well on a thyroid preparation, administered over a long period in small doses. I am in the habit of using the preparation produced by Dr. Beebe in the Cornell Laboratory. Many of these cases respond well to this remedy, combined with rest and symptomatic treatment.

Occasionally quinin hydrobromid can be alternated with the thyroid preparation. There is nothing special in the diet so far as I can see, except a diet that will relieve digestive embarrassment, if that be present. Occasionally ferrous iodid seems to be valuable. Some recently published observations by Wilson and Plummer of Rochester show that this type we so frequently see is a distinct pathologic and clinical entity. Wilson calls them toxic non-exophthalmic goiter and the changes in the gland as observed by him are not those of true exophthalmic goiter. They do not develop the eye symptoms. Such cases go for ten or fifteen years with symptoms of hyperthyroidism and yet never develop characteristic exophthalmic goiter. The pathologic changes are hyperplasia, regeneration, and the formation of connective tissue, and of course this gives rise to perverted secretion. The physiologists ought to be able to help us considerably in this study.

DR. OTTO JOACHIM, New Orleans: Twenty-five years ago Fraenkel called attention in a clinical case to the reduction of goiter on the same side as that on which he reduced a hyperplastic inferior turbinate. This was looked on at that time as a very extraordinary result and not held in any causal relation. The idea was not followed up. We should be very grateful to Dr. Beebe for calling our attention more specifically to the pathologic condition following infections of the nose and throat. More strongly than ever, the theory of disturbed internal secretions advanced yesterday by Dr. Beck appeals to me. We need not look necessarily for a focus of a purulent type to explain these disturbances. A great many will be accounted for on the ground of disturbed defective or overactive internal secretions which in turn affect the thyroid.

In our part of the country we see a great deal of thyroid trouble, especially in young people, and we are often confronted with the necessity of relieving these patients without operation. I am also of the opinion that, in the earlier stages, these cases are amenable to therapeutic measures. Operation is not always indicated and the diagnosis of the beginning of the trouble is of extreme importance. The importance of these relations between abnormal conditions of the nose and throat and hyperthyroidism, however, are such that we need thorough laboratory investigations to clear up the matter. Of course, as laryngologists, we are not necessarily competent and have not always the opportunity to properly study these cases. They come to us and then disappear from our observation. The final light must come from the internist who has a better opportunity for this study.

DR. GEORGE E. SHAMBAUGH, Chicago: Dr. Beebe brings out the importance of the specialist cooperating with the internist. I emphasize this because there has been too great a tendency toward the development of special hospitals, where the eye, ear, nose and throat specialist does his work isolated from close association with other fields of medicine. The few advantages in this arrangement are far outweighed by the much greater disadvantages arising through the lack of cooperation with other branches of medicine. The best arrangement, and the one in which our best work is done, is in a general hospital, where our work is carried out in cooperation with the internist, the neurologist, the general surgeon, the dentist, etc. In the Presbyterian Hospital, in Chicago, we have been interested in this relation between hyperthyroidism and the faucial tonsils. I have several times been requested by the internist to remove the tonsil in these cases, and when asked to operate in such cases, I do so, nor do I attempt to hunt over the tonsil for palpable evidence of foci of infection before consenting to carry out the internist's request. The possibility of abnormal tonsils being the focus for the changes in the thyroid is interesting. I have several times seen the disappearance of the hyperthyroidism in a remarkably short time after the removal of the faucial tonsils. It has been suggested that the relation may be reversed. If so I do not see why the goiter should disappear after the removal of the tonsils.

DR. JOHN F. BARNHILL, Indianapolis: This subject is entirely too new to have data that is worth while. It is only in the past two years that we have been adding to our case

records, or at least that I have, the condition of each thyroid at the time of making the throat examination. Dr. Shurly recently, before the American Laryngological Society, expressed the belief that there is a relationship between hyperthyroidism, and tonsil and throat infections. Knowing that we were to have Dr. Beebe's paper, on my return home from this meeting of the Laryngological Society I looked up as many of the cases of hyperthyroidism in which I had operated for removal of the tonsils, as I could find. I found seven cases in which in the last three years I had removed the tonsils when this condition existed. In none of these cases, so far as I was able to judge, was the thyroid condition improved. One of these patients had been operated on in one of the large clinics for hyperthyroidism two years previously. The surgeon who did the operation had stated that the patient had enlarged tonsils which ought to be removed at once. When she had fully recovered from the thyroid operation I removed the tonsils. She was improved for a time. I saw this patient three days ago and the lobe of the thyroid opposite to the one which had been removed is now enlarged and she has very marked exophthalmos. This was interesting to me because one lobe of the thyroid had been removed and the tonsils had been removed, and yet she still has the condition of hyperthyroidism. I believe that there is a connection between tonsillar infection and hyperthyroidism in the same way, perhaps, as an infected toe or antrum or gall-bladder might bring about such conditions; that is, by lowering bodily resistance. It is our duty, therefore, to discover these cases early, because I am convinced from examination of the cases that I have recently made, that whatever benefit we are to get from removal of the tonsils must come from operating in an early stage of the thyroid enlargement.

DR. JOSEPH C. BECK, Chicago: The subject of the infections of the upper respiratory tract in connection with thyroid disease has interested me for some time and I am in a position to speak from experience on the subject in its entirety, for I follow these cases whenever hyperthyroidism is present. Dr. Barnhill said exactly what I would say with reference to the curing of any patient with hyperthyroidism by removal of the tonsils and I have had quite an experience in that line. I have seldom seen a case that did not respond by improvement, nor have I seen a single case that was difficult to operate on. One certainly would not attempt to do a tonsillectomy in a patient in a down-grade stage of hyperthyroidism. Tonsillectomy will do this; it will do what a single ligation of the superior thyroid artery will do; it is transitory. It puts the patient in a condition in which a thyroidectomy may be done. My statement concerning the tonsils as causing hyperthyroidism is based on a study of the sympathetic nervous system. It is believed that toxic elements, not necessarily pyogenic, either stimulate or depress the vagus and alternately the sympathetic and produce changes in the internal secretions. The pathologic changes in the thyroid itself, of course, we understand, the colloid changes, which are degenerative, and have nothing to do with an infective process.

DR. GEORGE F. COTT, Buffalo: My experience has been similar to that of Drs. Beck and Barnhill. I have operated on children of 10, 15 and 20 years of age and people as old as 69, and not a single one of these patients, thirty in number, have had any throat complaint or tonsillar or sinus trouble. So that I have reason to believe that the condition was not due to any infection of the upper respiratory tract. Dr. Beck told us what we may expect from disturbances of the internal secretions and, of course, these infections may cause disturbance of the internal secretions, but that may happen in other diseases as well as in goiter. Of all the patients I have operated on for goiter, not one complained of trouble with the throat or nose at any time. I want to make this statement from the point of view of a laryngologist as compared with that of Drs. Beebe and Jennings, and I think we have as much chance of observing these conditions as has the internist.

DR. OWEN SMITH, Portland, Maine: For fifteen years I have been interested in this particular line of work. The

question of diagnosis in these cases is particularly important to the laryngologist because a great many of them come to him before the symptoms become so pronounced as to attract the attention of the internist. In small cities the laryngologists are supposed to be better qualified to handle these cases than a great many of the so-called general practitioners, and they should not only be able to cooperate with the internist, but should be qualified to handle these cases both from a medical and surgical point of view.

A discouraging feature, from my observation, is that it is difficult to decide from the work of the internist and the surgeon just what is best to do in these cases; whether to treat them medically or to go on to the more radical surgical procedures. The medical treatment, in my experience, has been rather disappointing. I have followed, more or less, the work of Dr. Beebe and Dr. Forscheimer. The latter basing his work, perhaps, on the septic theory, has attained better results than in any other method of medical treatment. On the other hand, the radical surgical treatment at times is very disappointing, although sometimes the results are striking, the patient recovering rapidly.

DR. HENRY HORN, San Francisco: The propaganda of education which Dr. Beebe has presented is at this time very apropos. We, as laryngologists, possess a field of investigation which up to this time, so far as I know, has not been worked up, and inasmuch as the object of these meetings is to draw the general surgeon, the laryngologist and the internist into closer contact with our work, I desire to call attention to a problem which perhaps has not been sufficiently considered: the possibility of the tonsil as an organ of internal secretion. As specialists who remove hundreds of tonsils, we are possibly in a position to draw conclusions better than any one else, but, nevertheless, in the thousands that are removed, the opportunities for observation are seldom carried out in any systematic way. I only wish to call attention to the fact that there is a certain class of cases, especially in young women, in which removal of the tonsils will produce a condition closely related to what we know as the thyroid symptom-complex; tachycardia, intense nervousness, etc. Now, of course, that suggestion is immediately open to the objection that these cases may be cases of hyperthyroidism; I do not think so, and I think we should observe some of these cases and study them more closely with the internist.

DR. BURT R. SHURLY, Detroit: I have been much interested in this subject for five or ten years and I think there are certain points that we are very liable to neglect. Certain essential facts are necessary to be known, for in the equipment of the laryngologist certain facts of diagnosis in internal medicine are particularly valuable to us, if we can have classified knowledge and definite ideas of just exactly how we are to consider some of these problems that really belong to internal medicine and yet in which we have a great interest. In this way our equipment as laryngologists will certainly be very much improved. The great essential, it seems to me, is that we should consider an examination of the thyroid gland as part of our routine procedure in every case. A great many men will overlook the thyroid gland entirely, while if we will examine it anything of particular significance may be immediately followed up with further investigation. Dr. Beebe and Dr. Rogers of New York have certainly been the pioneers in developing this subject, and they have given us the greater part of our knowledge in this regard. Dr. Rogers has a fine history scheme which immediately concentrates one's investigation of the symptoms of thyroid trouble as it may be connected with any condition of the throat or nose. It is not claimed that diseased tonsils are the only cause of goiter. We all know that hyperthyroidism is very frequently associated with nervous shock, overwork, miscarriages and postobstetric conditions. As Dr. Jennings has said, in Michigan we have a considerable number of mild cases, and many of these are overlooked. It seems to me the prophylactic effect of removing the tonsils is quite effective. If you can prevent recurrent tonsillitis you prevent the acute condition again and it is the acute condition that makes the trouble.

Will Dr. Jennings say something of the essentials of medical treatment?

DR. S. P. BEEBE, New York: It was not my purpose to advocate the removal of tonsils and adenoids as a cure for exophthalmic goiter. If any one has so understood my statement, I wish to correct it. What I have said about the frequent occurrence of infected areas in the nose and throat is derived from the history of approximately 3,500 patients who have had this disease. It is quite possible for one to have had a number of patients with thyroid disease who have not at the same time had either sinus or throat infections. Nevertheless such infections are a most common accompaniment of thyroid disease, and, in my judgment, constitute an important factor in maintaining a condition which favors overactivity of the thyroid gland. One cannot see the effect of repeated infections in these patients without being impressed with their importance. I wish, however, to impress the importance of making every effort to discover the beginning of thyroid disease. As specialists you will frequently be consulted by parents who bring their children to you for nose and throat infections. The patient may not have been seen by an internist at any time and, unless the physician who does see them examines the patient with reference to his general condition, as well as to determine the condition of the nose and throat, many diagnoses that might be made will be missed. Routine examinations of the nose and throat should include an examination for any possible enlargement of the thyroid gland. Simple tonsillectomy or removal of adenoids is not all that is necessary to do in the line of treatment even in these early cases, but the custom of regarding a thyroid enlargement as of little medical importance unless accompanied by marked or severe symptoms is an error too commonly made at present. When the thyroid disease is well developed and the gland itself has undergone a marked pathologic change, there is no reason to suppose that a cure will be obtained simply by attention to the nose and throat infections. A recurrence of thyroid disease after repairing the nose and throat does not controvert the necessity for attention to such a condition. The most important thing in this work is to prevent the serious thyroid disease which has insidious beginnings, and these patients so often come to the nose and throat specialists first that it is of decided importance that the beginnings of thyroid disease should not be overlooked at a time when the patient's recovery is a comparatively simple matter.

THE USE OF CELLULOID SPLINTS IN THE TREATMENT OF DISEASES OF THE NERVOUS SYSTEM *

G. WILSE ROBINSON, M.D.
KANSAS CITY, MO.

In the treatment of diseases of the nervous system as in the treatment of other diseases, the attending physician must measure the success of his treatment by the preservation of the life of the patient and the restoration of function in the anatomic structures diseased.

Of those diseases which endanger life and disable the patient by paralyzing muscles, groups of muscles and entire members, poliomyelitis stands as the most common type. During the acute stage of this disease the patient should rest in bed, the nares should be washed with a 1 per cent. solution of hydrogen peroxid, hexamethylenamin administered, and the pains controlled by the application of heat or by the giving of analgesics, if needed, and lumbar puncture done if there be signs of meningeal irritation.

After the acute stage is passed the physician must interest himself in and direct his treatment toward the restoration of muscular function and the prevention of deformities. The restoration of muscular function can be encouraged and facilitated by massage, electricity and exercise. The paralyzed muscles should be tested with the faradic current and if they respond to faradic stimulation two weeks after the onset of the paralysis, recovery should be expected. If they do not so respond, recovery may take place if the proper treatment be instituted. The electric current which gives the best therapeutic results is the galvanic. It is the characteristic tendency of poliomyelitis to paralyze individual muscles and groups of muscles, and it is for this reason that deformities are so prone to occur.

The prevention of deformities is the most important part of the after-treatment of poliomyelitis. They occur with great frequency, and are to a much greater degree responsible for the permanent disabilities of the patient than are the paralyzes. In but a small percentage of patients is the paralysis so extensive and disabling in character as permanently to prevent walking, but the deformities so cripple a large percentage of patients that walking is very difficult or impossible. General acceptance is given to the idea that paralyzed muscles should be placed and fixed in the position of rest, should not be overstretched by the action of non-paralyzed antagonistic muscles, and should be supported in order that they may be used as their condition will permit.

Numerous and various methods have been suggested by which rest, relaxation and protection of the paralyzed muscles can be secured. Simple rest in bed is considered adequate by some, others apply a splint so as to fix the limb in normal position, while others splint the limb so that the paralyzed muscles are completely relaxed and the antagonistic muscles are hyperstretched. I do not presume to say that any of these methods are bad, either absolutely or relatively. Any one of the three methods can perhaps be applied with success to individual cases.

It is my opinion that all limbs paralyzed by poliomyelitis should be fixed in the normal position of rest, so that the paralyzed muscles cannot be overstretched, and held in such position by a splint which gives sufficient support to enable the patient to walk during the stage of repair, thus applying a physiologic stimulus to aid the recovery of the affected muscles.

Contractures begin to develop early in poliomyelitis and protection should be given to the paralyzed muscles from the onset. The most common of the early deformities is toe-drop, occurring as a result of the contraction of the flexors of the toes and of the extensors of the foot, in the absence of the action of the opposing muscles. As this deformity is hastened by the weight of the bedclothes a cradle should be used when it is expected.

As soon as the pain has subsided sufficiently to enable the paralyzed structures to be handled without occasioning too much discomfort, a splint should be applied for the reasons given above.

As a material for the making of such splints I believe celluloid has many advantages. Celluloid splints are simple, effective and cheap, and most successfully meet all requirements. They keep the muscles at rest in a position of relaxation, prevent deformities and enable the patient to walk while repair is progressing. They can be worn both day and night with

* Read before the Section on Nervous and Mental Diseases at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

entire comfort, do not absorb moisture, are sufficiently strong to support an adult, and yet are very light—those for a child weighing from 10 to 14 ounces and those for an adult from 24 to 32 ounces—are readily removed in order that the limb may be washed, massaged or treated with electricity and can be reapplied without difficulty. In more than 85 per cent. of the cases the muscles of one or both legs are affected, but in about 40 per cent. they are affected in combination with the muscles of the trunk, arms and neck. In 15 per cent. of the cases the legs are not affected, but the celluloid splints can be applied to the arms, trunk or neck and perform the same functions as when applied to the legs.

CLASS OF CASES SUITABLE FOR SPLINTING

All cases of paralysis of the legs are suitable for splinting, except those with complete loss of power in the psoas and iliacus group and in the glutei. Those cases in which the back, lumbar and abdominal muscles are much affected are also unsuitable for splinting, but if there be considerable affection of the dorsal and abdominal muscles with little involvement of the legs, a spinal jacket is very helpful. The extent of the splint must vary according to the degree of the paralysis. If the leg be extensively paralyzed, the splint should encompass the entire leg as high as the tuber ischii behind, the trochanter on the outer side and the ramus of the pubes on the inner side. If the paralysis be limited to the muscles below the knee a splint reaching to the knee will suffice.

Celluloid splints have been found most useful in the treatment of the paralyzes and in the prevention of the deformities of poliomyelitis, but they have a much wider range of usefulness. They are of benefit in the treatment of the wrist-drop or toe-drop associated with lead or alcoholic neuritis, or that from any other cause. They are also of value in the treatment of hemiplegia, with contraction and inversion of the foot, and in contracted conditions of the hand. They will prevent deformities if applied early in the diplegias of infancy and in myelitis.

The celluloid splint is of much value in the treatment of some conditions occurring in tabes, in hypotonia with hyperextension of the knee, they support the knees and enable the patient to walk. In Charcot's disease of the knee-joint they give support, so that the patient can walk without the danger of the knee suddenly giving way, and the fixation with pressure limits the extension of the disease and the effusion which often takes place within and around the joint. In order that the best results may be obtained the patient with Charcot's disease should rest in bed for several days before the cast for the knee is taken, so that the edema and swelling of the joint may subside, otherwise the splint will shortly be too large.

We are indebted to Calot¹ of Berck-sur-Mer for using and bringing celluloid splints to the attention of the profession. Gauvain² introduced them into England and used them in the treatment of tuberculous joints. To him belongs the credit of much of the improved technic in making them. Dr. Frederick Batten³ of the National Hospital for the Paralyzed and Epileptic, and of the Great Ormond Street Hospital for Sick Children, London, proved their great value in the treatment of poliomyelitis and other diseases of the nervous

system. Dr. Batten, relative to his experience with them, says⁴: "I have used them frequently during the past two years in the treatment of cases of poliomyelitis, and they have proved of the greatest service in preventing deformity and hastening recovery."

MAKING THE SPLINTS

The following processes are involved in making the splints:

1. The taking of the negative cast of the part to be splinted.
2. The making of the positive cast from the negative.
3. The building of the splint on the positive cast.

The details of these three processes are to be given, but I desire to emphasize the importance of the first process. The negative cast should be applied by the physician and it is essential that it be made properly, otherwise it will be useless.

THE NEGATIVE CAST

For the purpose of making the negative cast the following articles are required: a strip of lead $\frac{3}{4}$ inch wide and 2 or 3 feet in length, some oil, a strong knife with a sharp point, and some plaster-of-Paris bandages. For this purpose the ordinary surgical bandages are really not suitable. Batten recommends a bandage made of book-muslin, $4\frac{1}{2}$ inches wide and from 4 to 6 yards in length, loosely wound and not too heavily loaded with plaster.

The part of the body of which the cast is required is first shaved, if hairy, and then oiled. The strip of lead is oiled and adjusted to the point at which the cast is to be opened. The limb is now placed and held in the position in which it is to be fixed by the splint. As stated above, one of the most important functions performed by a splint to a disabled leg is to enable the patient to walk during the process of repair. If the leg be splinted with the knee hyperextended and the foot dorsiflexed on the tibia, walking will not be possible. The knee should be slightly flexed and the foot held exactly at right angle with the tibia. The plaster-of-Paris bandages are placed in warm water and after being squeezed out are wound round the limb, starting at the periphery and working up. The best results will be obtained if each bandage is taken continuously from one extremity of the cast to the other. If this be done the tendency of the cast to crack transversely will be much lessened. It is not necessary that the cast be very thick; four or five bandages for the entire leg of a child from 6 to 8 years old will be ample. The plaster will usually set in from three to five minutes. After it has set sufficiently a cut is made down to the lead. Before manipulating the cast be sure that all threads are divided, or a portion of the cast may be pulled out of place and the cast spoiled. The cut edges of the cast are now separated and the lead removed through the incision; the edges are still further separated and the cast is gently removed from the limb. In the case of the leg, if an assistant will grasp the toes and pull them forward while the cast is pushed backward little difficulty will be experienced.

After the removal of the cast the cut edges are carefully approximated and a single layer of plaster bandage wound round the cast from one end to the other, the lower opening being carefully closed with the bandage. This completes the negative cast and it is laid away to dry.

1. Calot: *Orthopédie Indispensable*, Paris, 1913.
2. Gauvain: *Brit. Med. Jour.*, 1913, i, 1200.
3. Batten, Frederick: *Lancet*, London, 1912, i, 80.

4. Batten, Frederick: *Clin. Jour.*, 1913, xlii, 5.

THE POSITIVE CAST

The time required for the negative cast to dry is from twelve to twenty-four hours; after it has thoroughly dried the positive cast may be made. The inner side of the negative cast is well oiled; a bamboo cane or small stick of wood of adequate strength to support the positive cast and several inches longer than the negative cast is placed down the center. The plaster-of-Paris is now mixed in the usual manner, poured into the cast and allowed to stand for about twelve hours. An incision is made through the single layer of plaster bandage, the cut edges of the negative cast separated and the positive cast removed. The positive cast is now ready for the molding of the splint.

THE MOLDING OF THE SPLINT ON THE POSITIVE CAST

As previously stated, to build the splint on the positive cast is not a difficult process and may be done equally well by the physician or nurse. The various articles required are as follows: stockinet or thin felt, gauze or book-muslin, solution of celluloid in acetone ("Gauvain's solution"—11 ounces of celluloid to 160 ounces of acetone, to which is added 3 ounces of calcium chlorid dissolved in 2 ounces of hot water, which should be added to the celluloid solution while still hot and well shaken), celluloid varnish (cellulose triacetate one part, acetone five parts), some leather for binding the splint and some boot-hooks.

METHOD

A layer of stockinet or felt is sewn over the positive cast. Over this is placed a layer of gauze or book-muslin, so cut as to conform to the shape of the cast. On this is painted a coat of the celluloid solution; another layer of gauze is applied, on which is painted another coat of celluloid solution; this process is repeated until from twelve to eighteen coats of celluloid solution are painted on as many layers of gauze, the number varying with the age of the patient and the character of the part to be splinted. Sufficient time should be allowed between the application of the successive coats of celluloid for the previous coat to dry. A few extra layers should be applied about the knee and ankle. After the final coat has dried a layer of celluloid varnish is applied. Two incisions are now made about $\frac{1}{2}$ inch apart and a strip of the splint removed at the point at which the opening is to be made. This permits of the removal of the positive cast from the interior of the splint. The splint is now ready to be fitted to the patient. It should fit perfectly, assuming that the cast was well made. It is usually necessary to cut away a small amount of the splint around the knee and ankle in order to facilitate its removal and reapplication.

After the fitting process is completed, the edges of the splint are bound with leather and boot-hooks are inserted. It is now ready for wear. The splint should be worn next to the skin as a stocking inside will force it out of place. It should be applied while the patient is still in bed, laced on and worn day and night, being removed twice a day for massage and passive movements. If it causes discomfort by undue pressure at any point, it should be stretched and manipulated so as to relieve the pressure. If relief cannot be obtained in this manner, some of the splint should be cut away rather than to put wool or leather inside the splint to relieve the pressure.

It is desirable that the patient be up and walking as soon as possible after the onset of the disease. Aided by the splints the average patient can walk at the end of the first month, without liability to deformity. A walking apparatus is usually necessary at first but many patients regain strength so rapidly that they are soon able to walk alone. A slipper or shoe should be fitted and worn over the splint, as walking is thereby made easier. Some patients with poliomyelitis recover so rapidly that the splints are no longer needed after a few months, while others may need to wear them even up to two years. If walking is not possible without support at the end of this time, a metal brace should be applied when the splints are discarded. In some cases of this disease there is never sufficient restoration to enable the patient to walk without some support. In those cases a metal brace will answer better after the splints have served their purpose.

CONCLUSIONS

Many patients with poliomyelitis are permanently disabled because of deformities. Celluloid splints prevent the deformities and aid in the recovery of the paralyzed muscles. They render the same aid in many other forms of paralysis and by affording support they give much comfort and greatly increase the efficiency of the patient with a Charcot joint and in extreme cases of hypotonia of tabes.

937 Rialto Building.

ANAPHYLAXIS FOLLOWING SKIN-GRAFTING FOR BURNS

H. L. UNDERWOOD, M.D.
LA GRANDE, ORE.

The case herewith reported is of interest, partly because perfect recovery followed, notwithstanding the extent of the burn and its systemic effects, and partly for the occurrence of certain phenomena analogous to if not identical with anaphylaxis. To quote Auer,¹ "While the investigator should be alert to note resemblances of reaction in the different species, he should be still more alert to discover new types of reaction." So far as I am aware there has been no effort to identify the reaction accompanying repeated skin-grafting over large areas with that of anaphylaxis, yet it seems clear that they are closely related if not identical, as the following case indicates:

History.—G. H., man, aged 25, driver, gave no evidence or history of constitutional disease of any kind. On the night of Nov. 14, 1910, he was burned by the explosion of a kerosene lamp. When seen by me shortly after the accident he was suffering acutely and presented burns from head to the knees with the charred night-clothes adherent to the flesh. The areas burned were: face, scorched but not blistered; neck, blistered and skin above right clavicle destroyed over an area of several square inches; right shoulder burned to third degree; right arm burned to third degree over two thirds its surface; right forearm burned to a blister; both hands badly blistered; all the right side and nearly half of the left side of the thorax burned badly, nearly all to third degree; about one-third of the entire back blistered, about one-third to the third degree; abdomen and groin on the right side burned to third degree, on left side, scorched; right hip blistered; right thigh, third degree burn over its inner aspect; external genitals completely blistered; left thigh, third degree burn over one-fourth inner surface; extensive areas burned to

1. Auer, J., in Forchheimer's *Therapeutics*, v.

large blisters over both thighs; knees, legs and feet free. I estimated that fully half of the surface of the body was affected.

Treatment.—Temporary dressings with moist compresses of sodium bicarbonate were applied and an opiate given. Next day Nietzsche's oil varnish was applied: lead oxid 1 part, linseed oil (boiled) 25 parts, salicylic acid 5 parts. The diet, for one month, was restricted to fluids. High rectal enemas were given once or twice daily. Digitalis and strychnin were given when the pulse indicated it. Skin-grafting was begun as early as the local condition warranted, skin being employed from the patient's brother, and later from friends and neighbors. In all grafting was done at twenty-two sittings and skin was furnished by seventeen different persons. The dates of the earlier grafts are as follows: November 26, 30, December 5, 9, 10, 11, 12, 13, 14, 15, 17. These earlier grafts took readily and thrived but just about the last date mentioned trouble began. An area about 6 inches square was grafted and did not take; then some of the old grafts began to "melt." Succeeding grafts also failed. Over a large area of the left thigh and back where no grafting had been done but autogenous epitheliation had progressed well, the tissue "mushed" and oozed blood badly. Hematuria appeared and lasted two days, and the heart impulse became irregular and weak. An examination of the blood, stained with eosin and methylene blue, showed distinct purplish granules in the red cells in enormous numbers. No blood-count was made, but there appeared to be a diminution per field in the white cells.

Having in mind some previous experiences with surgical wounds reopening coincidently with malarial attacks, I administered quinin for a few days although I could elicit no history of malaria. The patient's temperature rose irregularly in spite of rectal irrigations and laxatives till it reached 102, and 103 F. Pulse was 100 and regular.

Urine examination was negative for pus and albumin. Once or twice soon after the blood disappeared from the urine, the cold nitric acid test elicited the secondary ring, which disappeared on warming.

Egg grafts were next tried (December 24), and at first took well. The first was applied to the groin, and scarlet red used to stimulate a take. This I used in 8 per cent. ointment with boric acid or dusted in pure powder on the grafts and wound margins with the best results throughout the remainder of the case, and I attribute the good result attained partly to its use.

Egg grafts were repeated December 27, 28 and 31, January 2 (when the temperature rose to 100.3) and also January 7, 9 and 15. January 23 I ventured again to use a human graft, this from the patient's sister. A temporary take occurred but did not thrive well enough to offer much encouragement. The only human graft which thrived thereafter was a very small one from the patient's mother. The egg-grafts failed after the first few times and thenceforth I relied mainly on scarlet red and the patient's own powers of epithelization. It was remarked both by the patient and myself that the application of the later egg-grafts caused very profuse secretion which fairly floated them off at the end of forty-eight hours, however carefully applied, and simultaneously the patient's own epithelium appeared to be stimulated to unusual proliferation.

It might be inquired why I made the attempt to skin-graft a score of small areas rather than a few large ones. I did so partly because not all the areas were in suitable condition at once and also because none of the patient's friends could afford to be laid up, but there were many who would give a little skin under local anesthesia with ethyl chlorid. Further, when the early successful grafting was interrupted by sudden and prolonged failure and disaster described above, I feared to continue except tentatively and on a small scale. In the light of present knowledge of anaphylaxis it is probably advisable to do the grafting in as few operations as possible and conclude the work within a few days. This, too, in the case of extensive burns may be dangerous to the patient. The problem, in fact, is one of great difficulty. Desensiti-

zation seems to be possible experimentally and may become so practically. There is still much to be learned in the realm of anaphylactic reaction before we can solve the problems that face us.

One important feature of sensitization is that it may be inherited, Rosenau and Anderson having shown in 1906 that the female guinea-pig may transmit her acquired susceptibility to her young. I know of no evidence that this holds in case of the male parent.

The anaphylactic reaction is more accentuated in proportion as the species concerned are widely separated biologically. Thus Rosenau and Anderson report that guinea-pigs sensitized with egg-white from the hen react to a later injection of the white from a duck's egg, but the reaction is less marked than when horse-serum is used. Further, the discovery of organ specificity by Wolff-Eisner in 1904 opens new difficulties. He found that the guinea-pig may be sensitized by an extract of the lens of its own eye and will react later to an injection of extract of the lens of the other eye, while organ-extracts from other animals easily sensitize.

In the case here reported it is to be noted that not only did two sets of foreign tissue successively lose their power to be transplanted, but also in each case caused distinct reaction in the patient. Yet at the same time, grafts from the patient's sister took to a degree and one from the mother perfectly. One may infer that consanguinity has a favorable influence.

The active immunity acquired in the course of an infectious disease or through the administration of specific vaccines possibly affect the blood so as to permanently influence the reaction of the body toward foreign proteins. Purpura hemorrhagica following an acute infective fever may perhaps be a manifestation of anaphylaxis. In 1901 I reported² such a case of purpura of severe type following an attack of lobar pneumonia in a child aged 4. In that case the pneumonia began February 6 with a definite crisis on the tenth day followed by convalescence. The purpura began March 2 without fever or any symptom of a new infection or recrudescence of the old one. The temperature by March 12 had risen to 101 F., and the blood showed marked evidence of hemolysis. The hemorrhages were profuse and prolonged, involving both the skin and mucous membranes. Was the purpura a secondary infection, or a slowly developing lack of prothrombin or other essential blood-clotting element of the blood, or was it some sort of anaphylactic reaction? My experience thus far leaves me in doubt. One practical lesson from the burn case herewith reported would seem to be that scarlet red and stimulation of the epithelium of the individual are of prime importance.

The patient was under constant care for nine months, but to my gratitude and somewhat to my surprise made a perfect recovery without contractions or impaired motion and no appreciable scars.

Necessity for Vital Statistics.—Sound vital statistics are the fundamental basis of all public health work, and should be the fundamental basis of public health laws. A nation that does not provide for accurately registering the births of its children and the deaths of its citizens, places a low value on human life, and could hardly be supposed to attach much importance to the conservation of human life.—W. F. King, M.D., in *Jour. Indiana State Med. Assn.*

*Special Article*TWELFTH ANNUAL SUMMARY OF
FOURTH OF JULY
INJURIES

This week, for the twelfth consecutive year, THE JOURNAL presents statistics of deaths and injuries resulting from the celebration of the Fourth of July, with particular reference to tetanus, or lockjaw resulting from these injuries. With the rapid decline in

the blanks were returned from the hospitals with the statement that no cases were treated. From others only a few names were reported, whereas in previous years several pages were required to contain the lists.

Our thanks are extended to health officers, hospital superintendents, physicians and others for the careful reports which have made these statistics practically complete and the figures fairly reliable. The data are presented in the same manner as heretofore so that the comparison with the figures of previous years may be made.

FEWER CASES OF LOCKJAW

Only three cases of tetanus were reported this year as compared with four cases last year, seven cases in 1912, eighteen in 1911, seventy-two in 1910 and 150 in 1909. The returns this year are quite encouraging and give hope that deaths from this needless cause will soon cease.

The ages of the three lockjaw patients this year were 14, 13 and 10 years, respectively, and all were boys. In two cases the injury was on the hand and in the other on the knee. The length of time between injury

case but not until the day after the active symptoms had appeared, which is usually too late. The list of tetanus cases is given in Table 1.

DISTRIBUTION OF TETANUS

The tetanus cases by states are shown in Table 2. Cases occurred in only three states this year, no case being in any of the states which reported cases last year. There were cases in six states in 1912, ten states in 1911, eighteen states in 1910 and twenty-

five states in 1909. One case each occurred in Kentucky, Minnesota and New Jersey. The clearing up of deaths from this cause in the last few years as shown by Table 2 is really marvelous.

THE DEADLY BLANK CARTRIDGE

Blank-cartridge wounds, which have always been responsible for a large majority of tetanus cases, this year caused two of the three cases, the other case resulting from a gunshot wound.

As may be noted, on comparison of the statistics of this year with those of previous years (Table 3), there is a significant ratio each year between the number of tetanus cases and the number of blank-cartridge wounds. The large increase of injuries from this cause in 1909 resulted in a corresponding increase in the number of cases of tetanus. A reduced number of blank-cartridge wounds almost invariably brings also a smaller number of lockjaw cases. The smaller number of tetanus cases in recent years in proportion to the blank-cartridge injuries is doubtless due to the greater care in treating wounds from this cause and the more common and prompt use of tetanus anti-toxin.

TETANUS FROM INJURIES NOT CAUSED BY FIREWORKS

Besides the cases of lockjaw due directly to the use of fireworks, it is interesting to note those occurring during Fourth of July season which were due to penetrating wounds from other causes, such as nails,

splinters, crushing injuries, etc. There was a continued reduction in these cases this year, only sixteen cases being reported as compared with thirty-two cases last year. Tetanus germs were perhaps as prevalent as in previous years, the reduced number of cases from these other causes being likewise due doubtless to the more common use of tetanus anti-toxin.

OTHER DEATHS AND INJURIES FROM FIREWORKS

Besides the three deaths due to tetanus, thirty-seven persons were killed by various forms of fireworks, making a total of forty deaths, or eight more than last year, one less than in 1912, seventeen less than in 1911 and ninety-one less than in 1910. Although the number is low compared with previous years, still the increase over last year indicates a possible relaxation in the enforcement of the restrictions of last year. This year five persons were killed outright by firearms, six by explosions of powder, bombs or torpedoes, four by cannon and five from blood-poisoning, from rockets, or other forms of fireworks. The most serious fact presented this year is that sixteen persons, mostly little girls or small children, were burned to death by fire from fireworks, three of these being reported as due to supposedly harmless sparklers!

As heretofore, all accidents not due directly to the discharge or handling of fireworks or other means of noise production and display on or about the Fourth of July have been omitted. Table 6 shows a comparison of the causes of death aside from tetanus for the past ten years.

DISTRIBUTION OF INJURIES

In Table 7 a summary of all injuries, including tetanus, and of all causes, is given arranged by states. Beneath the totals at the bottom are given, for comparison, the totals for the eleven previous years and the grand totals for the twelve years. Table 8 permits the comparison by states of the total deaths and injuries for eleven years. The number of casualties

TABLE 6.—CAUSES OF DEATHS NOT DUE TO TETANUS

Year	Gun-shot	Fire from Fire-works	Powder, Tor-pedoes, etc.	Giant Crack-ers	Can-non	Other Causes	Total

this year was 1,506, an increase of 343 over last year and an increase of 518 of the casualties reported for 1912. This increase is seen in the majority of states. Pennsylvania had 487 casualties this year, a decrease of only 4 cases below last year but an increase of 222 cases over the number reported in 1912. New York had 250 casualties, or almost double the number reported last year. Illinois reported 95 cases this year, which is more than twice as many as last year, although it is still a great reduction below the enormous totals annually reported prior to 1912. Massachusetts and Connecticut reported, respectively, 87

and 77 cases this year, the largest totals in those states since 1910. The figures for the last three years are very small compared with the previous years for California, Indiana, Iowa, Missouri, New Jersey, Ohio and Wisconsin. Continued reductions are seen this year only in Missouri, Nebraska, Ohio and Washington. Pennsylvania still leads in having by far the largest number of casualties. Meanwhile, of the 487 casualties in Pennsylvania, 241 (about half) were reported from Philadelphia this year as compared with 340 in that city in 1913.

NATURE OF NON-FATAL INJURIES

There were 1,466 non-fatal injuries this year, or 335 more than last year and 519 more than 1912.

Three persons were totally blinded this year, thirteen lost one eye each, sixteen lost legs, arms or hands, and sixty-seven lost one or more fingers. As there has been a considerable increase in the total number of non-fatal injuries, so have the totals of these more severe injuries been increased. This year 402 injuries were due to the giant firecracker, which continues to hold the first place as a cause of lacerated wounds and was responsible for most of the losses of eyes, hands, and fingers. A surprisingly increased number of injuries were caused by firearms this year, 231 cases being reported including five deaths. As usual, many of these injuries were caused by stray bullets from the reckless use of firearms by other persons. The use of cannon, including many of the improvised

* Kind of fireworks causing six tetanus cases unknown.

† Kind of fireworks causing 24 cases of tetanus unknown.

variety, resulted in 143 injuries this year, including four killed. In the twelve years, a total of 42,786 persons—the equivalent of over forty regiments—were killed or injured in the celebration of the Fourth of July.

TOTALS IN CHIEF CITIES

Table 9 shows the number reported killed and injured in our largest cities each year and the totals for the past eight years. The cities are arranged according to their population as given by the United States census in 1910. This table is of particular interest, since the results in each city in which prohibitive or restrictive ordinances have been adopted

can be seen. Prohibitive ordinances were enforced in Baltimore, Boston, Chicago, Cleveland, Minneapolis, Newark, St. Paul, Toledo, Trenton, Washington and elsewhere. Restrictive measures were used in New York, St. Louis, Pittsburgh, Buffalo and elsewhere. Philadelphia reported four deaths this year, Chicago reported three, Buffalo reported two, and one each was reported for New York, St. Louis, Pittsburgh, Newark, N. J., Scranton, Pa., Springfield, Mass., Tacoma, Wash., Duluth, Minn., and Peoria, Ill., making a total of eighteen deaths in twelve of our eighty-four largest cities, as compared with seven killed last year, twelve in 1912, sixteen in 1911, forty-three in 1910 and eighty in 1909. For the last four years Philadelphia has been the only large city having

more than 100 injuries, having reported 237 this year, a decrease of 103 below last year. Altogether 681 non-fatal injuries were reported for these large cities this year, as compared with 854 last year, 522 in 1912, 774 in 1911, 1,457 in 1910 and 2,936 in 1909. A slight increase over last year is seen in the records of some of these cities, although others, notably St. Louis, Boston, Baltimore, Pittsburgh, Buffalo, Milwaukee and others, have brought the returns considerably below last year's record. Of these eighty-four cities, twenty-three have a record of six or more injured, two less than last year, and twenty-four less than 1909. Twenty-four of these cities had a clean record this year, as compared with thirty-one last year, thirty in 1912, twenty-four in 1911, and eighteen in 1910. Probably the most marked reduction in the number of injured in the last few years have been in Chicago, St. Louis, Boston, Pittsburgh, Milwaukee and Newark. From Newark no casualties were reported in 1912 and 1913 and only two this year, a decided contrast to the record of 1909, when 150 were injured and one person was killed. It is noteworthy that nearly half of all casualties this year were in sixty-two of these larger cities.

WHERE THE RESPONSIBILITY RESTS

As has been repeatedly stated in these annual reports, for the great majority of Fourth of July injuries, *the responsibility clearly rests with city governments*, since the employment of death-dealing methods of celebration is subject to their regulation. It is clearly the duty of city authorities, therefore, to decide whether or not the maiming of hundreds, the agonizing deaths from lockjaw and the burning to death of little children by fire from fireworks are to be continued. Rigidly enforced prohibitive ordinances in sixty-two of our largest cities, therefore, would do much toward doing away with this national disgrace. Prohibitive ordinances are most effective and permanent, as shown by the results in Baltimore, Cleveland, Newark, Trenton, Chicago, Washington and elsewhere, and even restrictive ordinances, if they could be rigidly enforced, would have good results. But the enforcement of restrictive measures is difficult and requires constant vigilance on the part of the police. By the sound it is difficult to know whether an explosion is due to a firecracker 3 inches long or to one 5 inches long, or whether it is due to some other forbidden form of fireworks. Again, restrictive ordinances are usually looked on as half-way measures and are not expected to be enforced. Not so prohibitive ordinances, however, under which any explosion is recognized at once as a violation of the law. Again, ordinances which are merely restrictive are ineffectual since the smaller firecracker and sparklers which have been considered so harmless caused the fires this year by which sixteen children, mostly little girls, were burned to death.

CONCLUSIONS

In spite of the slightly reduced number of tetanus cases this year the returns are somewhat discouraging. The increased number of killed and injured indicates a relaxation in the enforcement of the ordinances which were so ably enforced two years ago. Instead of a relaxation of restrictive measures, the use of fireworks in the celebration of the Fourth of July should be strictly prohibited. To kill outright forty persons and to wound and maim 1,466 others is not a very fitting token of our thankfulness for the

and murder? The results of two years ago show plainly that these evils can be entirely done away with. It is hoped that city officials will continue their prohibitive measures until this desirable end is attained.

SATURDAY, AUGUST 29, 1914

THE FOURTH OF JULY CELEBRATION IN 1914

The Fourth of July has again come and gone. A sufficient time has passed to collect and to verify all reports of deaths and serious injuries. All cases of tetanus developing from injuries received in the celebration have been recorded, and the tabulated statistics of all casualties are printed this week on another page.

DEATHS AND INJURIES THIS YEAR

The returns show a continued increase over the casualties of two years ago, there being 1,506 this year as compared with 1,163 last year and 988—the lowest number—in 1912. There were 40 deaths this year as compared with 32 last year—the lowest number—and 41 in 1912. There were only 3 cases of tetanus—the lowest number—compared with 4 last year and 7 in 1912. These returns are very low, however, when compared with 130 cases of tetanus, 215 deaths and a total of 5,307 casualties, which was the record for 1909, only five years ago. Again, the fact that there were two days for celebration both last year and this (Sunday coming next to the holiday), may have had considerable to do with the comparatively slight increases of the last two years.

EVIDENCES OF PROGRESS

In spite of the slight increase in the numbers of killed and injured there are abundant reasons why those who are laboring for better forms of celebration should feel encouraged. Never has any cause been taken up so effectively by the public press as has this movement for a "safe and sane celebration of the Fourth of July"—an expression which has become so familiar in a few brief years. Never before has public sentiment been so unanimous or positive as in the overwhelming demand for a cessation of the noisy and destructive methods of celebration. And this year these evidences were more marked than ever. Besides the splendid service rendered by the newspapers in the work for reform, societies and associations, municipal, state and national in their scope, have been unusually active.

PROHIBITIVE MEASURES

In at least eight states—Arkansas, Indiana, Kansas, Nebraska, New York, Ohio, Pennsylvania and Texas

—just prior to the Fourth, the state fire commissioners sent special communications to the cities and towns throughout their states urging that the use of fireworks be discontinued or carefully safeguarded. In one state, Kansas, a model prohibitive ordinance was circulated which, according to the report, was adopted and enforced in over a hundred cities. This is a plan worthy of being followed elsewhere. It points to the prompt solution of the problem since the control of the use of fireworks clearly rests with city and town governments. Reports of the enforcement of prohibitive measures came from hundreds of cities in all sections of the country. This positive method of stamping out lawlessness, noise and destruction is clearly sweeping the land. That many of our larger cities have greatly improved their records in recent years by such measures may be noted in Table 9 on page 781.

NEWER AND BETTER METHODS SUBSTITUTED

Mere prohibitive measures have been surpassed in effectiveness, perhaps, by the wide adoption of better forms of celebration. Band concerts, picnics, parades and programs of various sorts have never been so generally in evidence as on the Fourth of July this year. This is the strongest indication that the reform is to be permanent. Never before has there been so general a display of flags in both public and private places. From all over the land came reports showing the cessation of noise, the absence of fires, formerly so common, and less need of constant vigilance by the police to restrain the more noisy celebrants. From everywhere came comments regarding the absence of deaths and injuries from the use of fireworks. How different from the awful results reported annually up to only a few brief years ago!

SIGNIFICANCE OF THE CHANGE

The watchword of this country has been personal liberty, which was heralded to the world by the Declaration of Independence, the signing of which is celebrated on the Fourth of July. The manner of observing this day, therefore, may be taken as a fair index of other tendencies in our national life. The individual was at liberty to celebrate the Fourth of July just as he was given the widest freedom in religion, in business and in other walks of life. But as the absence of restrictions led to abuses in the business world, so unlimited freedom gradually led to abuses in celebrating our Independence Day. The nation is learning that the greatest liberty to the greatest number demands that certain restrictions be placed on the liberty of the individual. In order to correct abuses in the business world in recent years much publicity has been given to political and commercial trickery and graft in high places and low, and there is a decided trend toward improvement.

The liberty to use fireworks in the celebration of the Fourth of July gradually degenerated into an annual orgy during which hoodlums held free license to kill,

to maim and to destroy. So general and so free had the use of fireworks become that even babes were suffered to handle fireworks, so often deadly even to adults accustomed to handling them. So bad had conditions grown that the celebration was annually demanding a toll of hundreds of children dying in the agonies of lockjaw, burned to death, shot down or otherwise slain, while thousands of others were blinded, maimed for life or otherwise injured.

BEGINNING OF THE CHANGE

So settled was the nation in this annual holocaust that it had come to be looked on almost as essential, and it required that the awful results be given publicity by *THE JOURNAL* time and time again through six years before the public could be induced to shake off its lethargy, and before any check could be placed on the crimes being committed annually in the name of patriotism. For six years *THE JOURNAL*'s reports with a few exceptions seemed to fall on deaf ears. A notable exception was the *Chicago Tribune*, which as a news feature for several years immediately following the Fourth had published unverified figures of the deaths and injuries. In spite of reports, however, the total casualties continued to increase until in 1908 there were 5,623 people killed and injured! In that year *THE JOURNAL* in its report published the returns from the forty-two largest cities. The figures revealed the fact that a great majority of the deaths and injuries were clearly due to lawlessness and disorder permitted in those cities. The corollary was also made clear that the governments of these cities were responsible for such casualties, inasmuch as they could be prevented by the enforcement of prohibitive measures. From that time on a wave of public opinion demanding a change of methods has been gathering and has grown with each succeeding year. This year the demand has been so decided as to leave no room for doubt as to the final outcome—the nation is to be freed from this annual holocaust in the name of American freedom.

THE CELLS IN COW'S MILK

The importance of cow's milk in the dietary of the well and the sick alike, and its indispensability as an article of food in the nourishment of a great group in our infant population tend to keep alive a wide-spread interest in the quality and purity of the available supply.

The significance of bacteria in milk, their influence in modifying its keeping properties, their possible danger as sources of infection—all of these facts have become a part of the common store of knowledge. Information concerning them has been spread broadcast, in magazines and daily newspapers. The problem of other structural elements in milk has not reached the public eye to the same extent; indeed, it has scarcely passed beyond the stage of scientific inquiry.

Many of the secretions of the body contain cells discharged from the tissues, and these cells in general are of two kinds: (a) epithelial cells discharged either from the secreting portions of the glands or from the lining of ducts or general epithelial surfaces, and (b) leukocytes which make their way through the walls of the capillaries and the lymphatics into the epithelial layers which produce the secretion of the gland and, finally, into the secretion itself. Under certain pathologic conditions the discharge of these cells may increase greatly above the normal amount. Milk ordinarily contains such cells. They were first described in connection with colostrum under the name of colostrum corpuscles.¹ American investigators² long ago called attention to the occurrence of leukocytes in market milk; and by speaking of them as "pus" cells (as is commonly done of leukocytes in urine) an imputation of possible danger was early placed on the fluid containing them. The question of the sanitary significance of the cells in milk has since then assumed considerable importance. A great deal of confusion in the discussion of the nature of these cells and their hygienic significance has been due to the assumption by many investigators that the presence of the cells under any conditions is a pathologic phenomenon and therefore undesirable. As a matter of fact the leukocytes which have passed through the epithelial lining of the alveolus in some part of the mammary gland under normal conditions are not pus cells any more than leukocytes in the lymph and blood, saliva and other secretions are pus cells.

As often happens in the progress of experimental research, imperfect methods of investigation have furnished apparently conflicting answers to the questions here involved. At one time the sediment of milk was depended on to disclose the presence of the cells. Subsequently it was found that many of these may be missed by this method of examination because they may rise with the cream layer and thus fail to appear in the sedimentary deposits. The whole situation, which is evidently in need of revision and supplementary study, has been reviewed by the bacteriologist of the New York Agricultural Experiment Station at Geneva.³ The evidence thus far obtained indicates that the largest average number of cells occurs in colostrum milk, though equally large numbers of cells occasionally occur in milk drawn at any time during the lactation period. Several very high cell-counts have been obtained from the milk of animals nearing the end of the lactation period, and the evidence given indicates that such high counts are more common during the latter part of the period than during its height; but the average cell-counts for the latter part of the period do not seem to be markedly higher than

2. Stokes, W. R., and Wegfarth, A.: The Microscopic Examination of Milk, *Med. News*, 1897, lxxi, 45.

3. Breed, R. S.: Cells in Milk Derived from the Udder, New York Agric. Expt. Station, Bull. 380, March, 1914.

the average cell-counts for the earlier part. There are marked daily variations in the number of cells discharged, the cause or causes of which have not yet been discovered. No constant relationship holds between the number of cells discharged in the fore-milk and the number discharged later in the milking process. There is a constant increase in the number of cells discharged in the strippings, the cause of which is not yet clear. The four quarters of the udder do not act as a unit in the discharge of the cells, but show as wide variations in number and character of the cells discharged as do separate udders.

The number of cells found in the milk of an ordinary dairy may come as a surprise to many. Out of the 122 cows whose milk has been examined, 59 were found to give cell-counts under 500,000 per cubic centimeter, 36 gave counts between 500,000 and 1,000,000 per cubic centimeter and 27 gave counts of over 1,000,000 per cubic centimeter. The average cell-counts for all of the cows was 868,000 cells per cubic centimeter. The milk of all the cows was normal in appearance and was sold or used by their owners, who had every reason to suppose that the milk was normal milk. Milking-machines, which are being operated more and more extensively in the dairy industry, have been charged with inducing a greater exodus of cells into the milk owing to the vacuum that these mechanical devices create. Dr. Breed states that several things seem to indicate that the number of cells present in milk drawn by a vacuum machine is somewhat less than the number present in hand-drawn milk. The results obtained show that there is no reason for thinking that changes in the vacuum or high vacuums may, in themselves, cause the discharge of excessive numbers of cells, or that high vacuums may draw blood from the interior of the udder.

The leukocytes predominate among the cells. The epithelial cells and fragments are presumably discharged because they are worn out or dislodged in the process of the secretion of the milk. The reason for the presence of the leukocytes is not so clear. By analogy with known leukocytic wanderings in certain pathologic states it has been widely held that the blood-cells are attracted into the milk by the presence of bacteria in the udder, especially by the particular kind of bacteria known as the pus-forming streptococci. This belief has arisen because of a large body of evidence which indicates that the milk of cows suffering from mastitis caused by a streptococcic infection, ordinarily, if not invariably, contains large numbers of cells. Dr. Breed has pointed out, however, that no systematic attempt has yet been made to discover whether there is a relationship between the number and kinds of cells discharged and the bacterial content of the udder which frequently harbors micrococci. He inclines to the belief that there are other reasons for the discharge of leukocytes in the milk than the pres-

ence of bacteria in the udder. These other reasons undoubtedly have to do with the physiologic conditions surrounding the process of milk secretion. The chapter dealing with the hygienic significance of the cells cannot yet be regarded as closed.

PLUMBING AND HEALTH

It is not surprising perhaps that old ideas concerning the causes of disease survive in some strata of society a long time after these ideas have been generally outgrown or discredited. All the same it is a little disconcerting to find that typhoid fever can still be complacently attributed to bad plumbing. When we read that "insufficient laws regulating plumbing and sanitation in Virginia, Maryland and the District of Columbia are largely responsible for the high typhoid rate and the prevalence of other diseases in the two states and the district," and again that "much of the fever and other forms of disease with which the health authorities are constantly wrestling is caused by noxious gases and vapors emanating from neglected or defective pipes in the homes of the people," we are inclined to rub our eyes and ask ourselves if the education of the community is really proceeding at the pace we sometimes like to believe. The assertions quoted above, however, were reported as made at the Association of Plumbers, Gasfitters and Steamfitters which recently met in Richmond, Va., and not at a convention of health officers or physicians.

It is hardly necessary to point out that typhoid fever—or any other fever—is not caused by bad smells, and that the small quantity of the gases of decomposition found in well-ventilated sewers has never been proved to exert any injurious effect whatever on health. A connection between plumbing and health has been shown to exist at just one point. Plumbing is of value to public health only so far as it removes human excreta from the immediate neighborhood of dwellings and so does away with the danger of fly-borne typhoid and other infection which arises from allowing infectious material to accumulate in family privy-vaults. Disease germs are not found in sewer air; indeed, it is difficult on physical grounds to see how they could get there. The "noxious gases and vapors," so dear to the plumber's imagination, are conspicuous by their absence in all perfectly constructed sewer systems, as every visitor to the great sewers of Paris and other modern cities well knows. "Defective plumbing" has about as much relation to public health as any other mechanical defect in house construction.

On the financial aspects of modern city plumbing ordinances we prefer not to dwell at this time. It is a well-recognized fact that these ordinances are drawn with no uniformity in our American cities and that what is required in one city may be prohibited in another. High authorities maintain that the system of

modern house plumbing which is made legally obligatory on housebuilders in many places entails a large, needless and altogether unjustifiable expense. Conceivably it is to the financial interest of plumbing supply houses—or somebody—to have the required system of plumbing as elaborate and as expensive as possible.

One feature of this situation deserves attention. It is plain that the most serious obstacle to the universal replacement in sewered towns of the dangerous privy-vault by the water-carriage system is the high cost of the plumbing. In this respect every unnecessary refinement and elaboration in plumbing outfits and legal requirements is a harm, not a help, to public health. The greatest possible simplicity and cheapness compatible with efficiency is what is needed in really "sanitary" plumbing, not a labyrinth of traps, vents and back-vents. If the plumbing interests really wish to aid the hygienic welfare of the community they can best do this, not by insisting on still more complicated devices and "inspections," but by simplifying and cheapening the cost of installing and maintaining the pipes and fixtures essential for carrying off the house wastes in a speedy and inoffensive manner. Finally, let us ask this question: To what extent do the plumbing ordinances in our American cities represent the prevailing opinion of public health experts and trained health officials, and to what extent do they represent the efforts of commercially interested individuals or organizations to entrench themselves behind the active if not always well-informed desire of the people to safeguard the public health?

MIXED VACCINE AND PHYLACOGENS

The noted advance in therapeutics shown in the development of vaccine therapy has brought with it grave dangers as well as advantages. We have, on a number of occasions, discussed in special articles and in editorials the dangers which threatened from the rapid commercialization of this new method. The unscientific character of mixed vaccines and of the mixed filtered products of a number of vaccines marketed as "Phylacogens" has been especially emphasized and the danger from their indiscriminate use pointed out. A little over a year ago we published a series of articles dealing with the whole subject in which the nature of mixed vaccines was described¹ as follows:

The mixed stock vaccine of commerce is a makeshift. It is offered as a substitute for correct diagnosis. Like all such makeshifts in science, it is doomed to failure. . . . A burden is being forced on the profession which will speedily assume the proportions attained by proprietary drug combinations. The menace cannot be counteracted unless physicians will accept the guidance of unselfish, non-commercial interests and refuse to purchase and use mixed commercial vaccines.

1. Bacterial Vaccine Therapy: Its Indications and Limitations, p. 37, reprinted from THE JOURNAL A. M. A., April 26-June 28, 1913, price, 19 cents.

This admonition to seek the guidance of unbiased scientific observers is deserving of special emphasis at the present time. Five weeks ago we published the address of the chairman of the Section on Pharmacology and Therapeutics, Dr. John F. Anderson,² one of our foremost workers in this branch of biologic science, in which attention was very forcibly drawn to the dangers involved in the use of biologic products of non-specific character. He says:

Bacterial therapy undoubtedly in some cases is a most valuable method of treatment; but when the claim is made that a combination of the dead bodies or the filtered products of a number of different bacteria are useful for the treatment of certain diseases with a different specific cause, it would seem that the suggestion closely approaches quackery.

Further he says:

Aside from the doubtful practice of the indiscriminate use of unproved methods of treatment, it has seemed to me that a great injustice is done the patient by their use, since some of the preparations that have been widely exploited have been shown to be harmful in certain instances and even to have caused death. So the first step in attempting to remedy conditions is to awaken the physician to the importance of ignoring the claims of those who are pushing these new methods until their usefulness and harmlessness has been clearly demonstrated by those best in a position to do so.

As a result of scientific methods in teaching therapeutics, physicians have gradually given up almost entirely the use of "shotgun" prescriptions and now prescribe a drug or a combination of one or two drugs, each given for the purpose of exerting a definite action. On the other hand, the purveyors of bacterial vaccines have gradually increased the number of different bacteria in their mixed vaccines until some of those now advertised for sale contain as many as seven different kinds of bacteria, and some of the "Phylacogens" contain the filtered products of at least eleven bacterial species!

Under the present federal law there does not seem to be any way in which the federal government can do more than is being done at present. It is a case in which the physician becomes the sole guardian of the patient committed to his care. He is the one and only responsible individual. He cannot throw the blame for bad results back to the manufacturer. When he subjects his patients to the possibility of harm by the use of these unscientific and dangerous preparations, the physician assumes the responsibility, whether he wants to or not.

If physicians would report their failures when these vaccines are used, and especially report the fatalities consequent on their use, with the name of the manufacturer of the particular product used, we are quite sure there would result a lessening in the enthusiasm of the purveyors of these products.

When tempted by the optimistic statements of the interested manufacturer of these mixtures to give them a trial the physician should remember that the

2. Anderson, John F.: Some Unhealthy Tendencies in Therapeutics, THE JOURNAL A. M. A., July 4, 1914, p. 1.

warnings of disinterested scientists are of far more value than uncritical clinical reports put out under commercial auspices.

This we quote from a recent book by Victor C. Vaughan,³ President of the American Medical Association:

Every time an unbroken protein is introduced into the body it carries with it, and as a part of it, a poison. From the very careless, rash, and unwarranted way in which "vaccines" of most diverse origin and composition are now used in the treatment of disease, this matter certainly cannot be understood or its danger appreciated by those who subject their patients to such risks. It should be clearly understood that all proteins contain a poisonous group—a substance which in a dose of 0.5 mg. injected intravenously kills a guinea-pig. This poison is present in all the so-called "vaccines" now so largely used, and it is not strange that death occasionally follows the use of "Phylacogen" or similar preparations. Not only do these proteins contain a poison, but when introduced parenterally the poison is set free, not in the stomach, from which it may be removed, but in the blood and tissues. It is possible that vaccine therapy may become of great service in the treatment of disease. Even now there are occasional brilliant results which are reported while the failures and disasters are not so widely advertised.

Such a warning as this quotation contains, from a man so eminent as Dr. Vaughan, merits and should receive the careful attention of medical men; at least it should have as much weight as the "clinical evidence" spread broadcast among our profession by commercial houses.

THE OPIUM ALKALOIDS AND DIABETES

Opium preparations have long been used in diabetes, and there is a wide-spread belief that they are frequently efficient in diminishing the excretion of sugar in this disease. Data might readily be cited from the literature of clinical medicine to show apparently advantageous results following opium medication. No satisfactory explanation has yet been furnished of the manner in which excretion of sugar is diminished. It has been suggested that the alleged beneficent influence of the drug is attributable in a general way to its well-known sedative action on the nervous system. This hypothesis contains, at least, something tangible, in view of the fact that more or less ill-defined conditions of nervous irritability have been said to produce certain types of diabetes. Now that the investigation of the sugar-content of the blood has assumed an importance as great as, if not greater than, the quantitative determination of the urinary sugar, the problem of the possible mode by which opium acts in this connection is presented anew. Dr. K. J. Otto af Klercker of the medical-chemical institute of the Swedish University in Lund has accordingly studied the influence of the opium alkaloids on certain forms of experimental hyperglycemia.¹ In the cases in which this

condition was elicited by injections of epinephrin or by the well-known *piqûre* experiment in which an injury to the roof of the fourth ventricle in the brain is promptly followed by glycosuria, no convincing effect attributable to the administration of opium products could be demonstrated. On the other hand, when an alimentary hyperglycemia was brought about by feeding unduly large quantities of glucose the inhibitory effects of opium products were clearly manifest. For example, repeated injections of opium alkaloids in quantities which of themselves had no demonstrable effect on the level of the sugar in the blood, nevertheless prevented the expected rise after the ingestion of sugar.

The newer studies of Magnus² and others have made clear certain effects of morphin on the movements of the alimentary tract which may serve to explain the inhibitory phenomena just referred to in connection with alimentary glycosuria. It is now known that this alkaloid greatly retards the discharge of its contents from the stomach into the small intestine, from which they are absorbed. It is apparent, therefore, that the antiglycosuric action of the opiates in diabetes may be due to the fact that the carbohydrates are not absorbed at the usual rate because they are not furnished in sufficient concentration through discharge from the pylorus. That the expected hyperglycemia does not develop in characteristic degree when opium products are administered may be due to the failure of the lower alimentary tract to be overloaded with readily absorbable carbohydrates within comparatively brief periods of time. Whether the facts here adduced will also suffice to explain the reduction in the output of sugar occasionally noted in human practice under similar therapeutic conditions, remains to be ascertained more definitely.

THE DANGER OF INFECTION FROM ICE

The modern practice of using iced food and drinks is so universal in this country that it is important to determine to what degree ice may be relied on as not carrying infection. When in the seventies and eighties of the last century it was shown that pathogenic bacteria might survive freezing, ice fell under suspicion as a possible medium for the transmission of disease; yet few epidemics have been ascribed to it, and the evidence concerning these has been regarded as inconclusive. H. S. Cumming¹ in a recent article makes a study from the point of view of the source of ice, the physical and biologic changes accompanying or consequent on its formation, and the methods employed in its collection or manufacture and handling.

3. Vaughan, Victor C.: Protein Split Products in Relation to Immunity and Disease, 1913, p. 236.

2. Morphin and Constipation, editorial, *THE JOURNAL A. M. A.*, May 31, 1913, p. 1711. Magnus: *Arch. f. d. ges. Physiol.*, 1908, cxxii, 210.

1. Cumming, H. S.: Safe Ice, *Pub. Health Rep.*, Aug. 7, 1914, p. 2066.

Ice is either natural or artificial. Until recently, in order to secure clean, transparent artificial ice, it was necessary to distil the water used; thus destroying all disease-germs present. With the newer methods employed, filtration is held to be sufficient. Cumming remarks that the fact, well known to chemists, that during crystallization nearly all extraneous substances are expelled from the crystal, was overlooked by sanitarians until recently. As Whipple says, "qualitatively the early bacteriologists were right; quantitatively they were wrong." In the formation of natural ice, most of the impurities are expelled into the waters of the pond or stream; and the same result is attained by the newer methods of artificial ice-making. By the "can" method, cans of water are immersed in the freezing mixture. As the freezing proceeds, the impurities are forced toward the center. In one of the newer methods, large cans are used, and the cakes of ice are cut into smaller ones, eliminating the dirty core. By another new "can" method, the impurities are expelled into about 6 inches of water kept liquid by agitation. In the "plate" method, the water is contained in large tanks, on one side of which are pipes containing the freezing mixture. The water freezes next the pipes in plates about 11 inches thick, and the impurities are expelled into the water beyond.

Some natural ice is undoubtedly derived from polluted rivers or ponds. Three great factors tend to purify ice from polluted waters: The first, as just mentioned, is crystallization. The second is temperature—the fact that freezing destroys a large percentage of bacteria. The third and most important is time. The longer the time intervening between the infection of water and its use (as water or as ice), the slighter the chance of the survival of the germs. On this score, natural ice, which is collected and stored for several months before shipment, has the advantage over artificial ice, which is usually marketed soon after it is made. Owing to these three factors—crystallization, temperature, time—clear, clean ice is of itself as free from danger as could be wished. Artificial ice made from pure water in clean, sanitary factories may be regarded as safe; so also may natural ice cut from reasonably pure deep ponds or lakes and stored under sanitary conditions. Artificial ice made from polluted water in dirty, insanitary factories is unsafe; natural ice cut from shallow polluted ponds or from grossly polluted rivers is also unsafe. Any dirty-appearing, cloudy ice may be infected as well as polluted; no such ice should be used in contact with food or drinks. Ice which is otherwise safe may become infected by improper handling—by being dragged across dirty streets or sidewalks or distributed by unclean hands. This is the great source of danger. We may practically eliminate danger by avoiding the handling of ice with dirty hands, by washing the ice with pure water, and by using only clear ice.

Current Comment

RADIUM IN CANCER

The papers on radium therapy in this and recent numbers of *THE JOURNAL*,¹ in addition to being instructive in themselves, are indicative of the interest in the subject at the present time. Radium therapy is going through the period of enthusiasm that Roentgen-ray therapy experienced ten years ago. This is perhaps inevitable, and after it the method will doubtless settle into its true place in therapeutics. It is not a new discovery that radium has interesting and useful possibilities. That was shown by Wickham and others several years ago. Indeed, we know enough from our experience now to predict with considerable assurance the extent of these possibilities. Radium is useful in numerous dermatoses; and, passing to the larger subject of cancer, it is indisputable that radium can be used successfully to destroy certain localized malignant growths, that is, growths on the surface whose entire extent can be sufficiently exposed to its energy. Extensive growths involving deep structures and disseminated growths are beyond its control, and there is no reason to believe that they will ever be brought within its control, for all experience with radium and the Roentgen rays has shown that these agents are useful in malignant growths only so far as they can directly destroy the cancerous tissue. In fact, there is every reason to believe that the extent and the limitations of therapeutic usefulness of the two agents are essentially the same, as are, indeed, the actinic energies of each. We have, then, a considerable experience on which to base our estimate of the usefulness of radium therapy, and from this experience there is no justification for the promise of relief in extensive cancer from the use of radium, or for the hope that with large quantities of radium we would be much nearer the solution of the problem of the cure of cancer in general than we are now. Radium has a useful therapeutic field, and it would be unfortunate for its therapeutic reputation to be damaged by exaggeration or injudicious enthusiasm.

A CURIOUS CUSTOM OF THE PARIS MEDICAL FACULTY

The historians of French medicine, Maurice Raynaud and others, have described at length the extraordinary amount of ceremonial (almost ritual) observances and banqueting which attended the graduation of Parisian medical students in the sixteenth and seventeenth centuries. Ernest Wickersheimer, librarian of the French Academy of Medicine, describes a singular custom of the old Paris Faculty

in the second half of the fifteenth century.¹ It seems that once a year, toward the end of winter, after the last elective disputation of the scholastic year, that is, at the beginning of Lent, the master regents of the Faculty betook themselves to the public warm baths at the expense of the bachelors in medicine. This observance is first mentioned by the historians of the Faculty, Feb. 27, 1473. It has been passed over by all other historians and was lost sight of in the seventeenth century. Jean Riolan, in his "Curious Researches on the Medical Schools of Paris and Montpellier" (1651), construing the Latin expression for the bath-house charges (*pro stuphis*) as an expense for stoves in the lecture rooms. The object of the custom was to afford a little recreation to the master regents, fatigued by the lengthy winter disputations, and of course, to make the festival complete, the visit to the baths was followed by a supper. In 1493, both bachelors and beadles were permitted to accompany the masters to the baths, and the same thing would have happened in 1499 had a bachelor not withdrawn, "an unbidden guest, because his bath bill had not been discharged." In February, 1496, it was still too cold for the Lenten tubbing; and in 1500, an epidemic of "inguinagra" (syphilitic bubo) was sufficient to scare the masters away from the baths, as happened in the case of the common bath pools of Germany in the same period. Wickersheimer states that this custom did not take root very deeply, and often the Faculty preferred to put the money obtained from the students *pro stuphis* to more practical uses. In 1479, the sum obtained was applied to the construction of schools; later, it was partly distributed among the master regents to liquidate the expenses of the banquets which always followed the disputations. From 1508 on, the amount collected was turned over to two master regents who had been designated as lecturers or readers (*lecteurs*).

AMERICAN VERSUS EUROPEAN POSTGRADUATE WORK

One of the compensations of the present European war is that it may compel Americans to seek out, to appreciate and to encourage a further development of the resources of their own country. Tourists who in other years sought the Swiss Alps will have time to see Colorado, California or Alaska; art patrons, deprived of the opportunity of buying dubious "old masters," will have a chance to do a real service to art by encouraging living native artists; students of music in the habit of studying abroad will be compelled to study at home, thereby bringing into prominence and encouraging better teaching in this country, and, last but not least, the multitude of physicians, compelled to break the habit of going to Paris, Berlin and Vienna for advanced medical instruction, may discover and call attention to the excellent facilities for postgraduate instruction in the United States. This is a good time to repeat what we have said before: that this country offers opportunities for postgraduate medical instruction equal to those afforded abroad, and some that are

superior, especially for American students. Foreigners have begun to appreciate the advances made in this country; we have had distinguished foreign visitors who came to learn, for instance, from American scientific work, hospital organization and surgery. It is true that, in the past, postgraduate instruction has not been so well organized in the United States as abroad. It has been said, also, to be rather expensive. Both of these objections are now being removed, with the organization of postgraduate instruction under university auspices in addition to other opportunities for postgraduate work. For instance, the Harvard Graduate School of Medicine offers for its summer term this year nearly two hundred different courses, including courses in all the numerous minor subdivisions of laboratory and clinical instruction. Tulane University, Louisiana, which also offers instruction to postgraduate students, is exceptionally situated in being able to give instruction in tropical diseases. Physicians whose plans for summer work have been deranged by the hostilities in Europe may have no reason to regret the enforced change if they employ their time wisely in America. On the whole, especially when the difference in the cost of travel is taken into consideration, a comparison of expense between American and foreign courses will be favorable to the former. Even before the present war broke out, it was acknowledged by men of high standing abroad that the future of medicine lies in America. It is to be hoped that one result of the interruption of communication between America and Europe may be that exaggerated prestige will no longer attach to one's having "studied abroad."

THE RADIO-ACTIVITY OF THE SARATOGA WATERS

In view of the fact that the sick of this and other countries have been extensively exploited in recent years by venders of so-called radio-active waters, the Bureau of Mines has done a public service by publishing the results of its examinations for radio-activity of the waters of Saratoga Springs, N. Y.¹ The results show that the activity of the different springs varies widely, some being more than twenty times as active as others. It is to be presumed that not even the most enthusiastic believers in the efficacy of radio-active waters would be inclined to attribute much remedial value to the radio-activity of even the strongest of them. Some are, however, much stronger in radio-activity than at least one of the widely exploited "radio-active" springs. Were the Saratoga Springs still in the hands of private individuals it is quite likely that these results would be exploited for commercial purposes. The work is stated to have been undertaken at the request of the commissioners of the state reservation at Saratoga Springs and, we assume, is published with their knowledge and consent. This procedure is far more creditable than that of the United States government in connection with the United States Reservation at Hot Springs, Ark.; the government has had the radio-activity of these waters

1. Wickersheimer, E.: *Gaz. d. eaux*, Paris, 1914, lvii, 751.

1. Moore, Richard B., and Whittemore, C. F.: *The Jour. Indust. and Engin. Chem.*, July, 1914, p. 552; abstr., *Propaganda for Reform Department*, this issue.

determined on two separate occasions, but only the vaguest and most meager information has been allowed to become public—just enough, in fact, to enable the bath-house owners and the government itself to exploit the results and to deceive the tens of thousands of sick who yearly visit these springs.

THE WAR AND THE MEDICAL PRESS

An evidence of one effect of the war is the small size of our British exchanges. This might be expected for no other reason than the lack of material for publication. The *British Medical Journal*, however, in its issue for August 15, gives as another reason the shortage of paper, which it states has become a very serious difficulty for the periodical press. The *British Medical Journal* has omitted entirely its epitome of current medical literature because it has received no German, Austrian or Russian exchanges for the previous two weeks, and very few from France. In addition to the difficulty in securing paper, because of irregular sailing of the ships, the consumption of paper by the newspapers has increased enormously because of the demand for extra editions. THE JOURNAL has received practically no German, Austrian or Russian publications, and but few French or Belgian periodicals since the war began. The Berlin Letter—mailed from Charlottenburg, July 31—arrived in Chicago August 25, too late for publication in this week's issue. No Paris and Vienna letters have been received of dates subsequent to the onset of hostilities.

Medical News

ILLINOIS

Still in Europe.—Drs. Frank J. Otis, Moline, and Dr. and Mrs. Karl F. Snyder, Freeport, are detained in Europe.

Personal.—Dr. Herman C. Stevens has been appointed examining alienist at Cook County Institution, Oak Forest. —Dr. Frederick W. Werner, Joliet, who has been critically ill with septicemia, is reported to be steadily improving.

Return from Abroad.—Drs. William L. Gray, Champaign; Heber Roberts, Belleville; Burdette E. LaDue, Ottawa; Ella Fitch Milligan, Ottawa; Mary L. Rosentiel, Freeport, and Charles B. Horrell, Galesburg, have returned from abroad.

Bathing Beach Closed.—The State Board of Health through its secretary, Dr. C. St. Clair Drake, has ordered closed the bathing beach for one-half mile on each side of one of the principal hotels at Fox Lake, Lake County. The sewage from the hotel empties into the lake near the beach and a number of cases of typhoid fever are believed to have been due to this cause.

Tuberculosis Notes.—The first clinic in the history of the Oak Forest Tuberculosis Sanatorium was held August 20 by Dr. Ethan Allen Gray in the Fresh Air Hospital. —Dr. Daniel Lichty, president of the Rockford Municipal Sanitarium to be located on a tract of land east of Sinnissippi Park, suggests the name of Oak Park for the institution. The site is about 15 acres in extent and 100 feet above the river with an ample forest area.

New Health Department Plans.—Tentative plans for the consolidation of several overlapping state bodies under the general title of the State Health Department, were considered at Springfield, August 19, at a conference of public health officials and others. The plans provide a state health department with a salaried health commissioner and an unpaid state board of health. The department is to include bureaus of vital statistics, foods, drugs, sanitary inspection, boards for the examination and licensing of physicians, pharmacists, dentists and nurses with power to revoke licenses

subject to review by the state board. The department is to be given sanitary control over barbers.

Chicago

Home from Europe.—Drs. Thomas J. Watkins and wife, Dr. Isaac J. Abt, Dr. Charles H. Solomon and Dr. Charles Gilbert Davis have returned from abroad.

Chicagoans Abroad.—Dr. Franklin H. Martin has reached London after an automobile trip from Munich. —Dr. Lloyd B. Crow, who has been studying in the Broussais Hospital, Paris, has gone to Fumay, a town on the French border near Namur and is caring for the wounded. —Dr. Robert J. Rize, with his wife and two children, has reached London after a trip through that portion of Belgium occupied by the German troops.

Personal.—Dr. Otto W. Lewke and daughter have returned from a tour of Alaska and the Canadian Rockies. —Dr. Harry M. Richter, who has just returned from Europe, delivered a lecture, August 21, in the amphitheater of the Maimonides Hospital on "Some Modern Advances of Medicine and Surgery," illustrated by stereopticon views. Similar gatherings are held at the hospital monthly, to which the medical profession is cordially invited.

Safety First Propaganda.—The coroner of Cook County has decided to issue the *Coroners' Safety Bulletin* weekly. The first issue deals with drowning and forecasts that one hundred and fifty-six persons will be drowned in Cook County during the year unless the educational campaign for public safety decreases this record. These figures are exclusive of suicides by drowning, of which twenty-two occurred last year. The greater part of the drownings reported to the coroner's office are during recreation or on picnics and the coroner urges that every child should be taught to swim and encouraged to enjoy it and that the sense of caution, prudence and calculation should be stimulated to the highest point for the maintenance of physical strength and alertness to overcome and escape danger, and the employment of judgment and alertness to avoid situations that are perilous to one's self and to others. This should include also training in first-aid, with special reference to drowning. The second bulletin is to be on accidental poisoning.

INDIANA

Loan to Health Board Authorized.—The city council of Indianapolis on July 28, authorized a temporary loan of \$77,000 for the use of the City Board of Health.

Indiana Physicians Abroad.—Dr. and Mrs. Franklin S. Crockett, Lafayette, Dr. Charles Melvin Mix, Muncie, and Dr. Manford M. Clapper, Hartford City, are detained in Europe on account of war conditions.

Home from Abroad.—Dr. and Mrs. G. Frank Holland, Bloomington; Drs. J. Rilus Eastman, William F. Clevenger and Thomas C. Hood, Indianapolis; Dr. Marcus Ravdin, Evansville; Dr. and Mrs. Harvey H. Martin, LaPorte, and Dr. Charles O. Bechtol, Marion, have returned from Europe.

Investigation of Insanity.—At a conference held in the office of the governor, August 7, the rapidly increasing number of insane, epileptics and other defectives in Indiana was discussed and the governor suggested the appointment of a commission to study the question, and stated that he would ask the legislature for authority to appoint such a commission.

State Association Meeting.—The annual meeting of the Indiana State Medical Association will be held at Lafayette, September 23 to 25. The sessions of the association will be held in the Y. M. C. A. Building and the Second Presbyterian Church. The Sunday before the meeting will be observed as "health day" and the pulpits of the city will be filled by members of the association.

Cause of Typhoid in Indianapolis.—The City Board of Health, Indianapolis, in investigating the typhoid situation in that city, found that fourteen cases were due to the careless handling of empty milk bottles. A family in which there was typhoid fever bought milk at the grocery and returned the empty bottles to the grocer, these were again filled by the dairy man and returned to customers, resulting in a large number of new cases.

Disease Prevention Day.—Arrangements are being made for the observance throughout the state of disease prevention day on October 2. Special emphasis is to be placed on the prevention of tuberculosis and representatives of the State Board of Health, Public Health Nurses' Association, State

Nurses' Association, State Medical Association, State Board of Education, State Society for the Prevention of Tuberculosis and State Federation of Clubs have been assigned positions on the initial committee of arrangements.

Society Incorporates.—The Indiana Society for the Prevention of Tuberculosis, filed articles of incorporation, July 28, in order to have legal authority to receive a bequest offered the society by an individual outside the state. The headquarters of the organization will be in Indianapolis and there will be a director for each congressional district of the state. The first board of directors is as follows: Mrs. George P. Decker, Evansville; Dr. Arthur A. Rang, Washington; Dr. Henry B. Shacklett, New Albany; Miss Mary Kennedy, Lawrenceburg; Prof. L. J. Rettger, Terre Haute; Dr. S. Edgar Bond, Richmond; Mrs. Jacquelin S. Holliday, Indianapolis; Miss Luella Anderson, Muncie; Dr. Fred A. Dennis, Crawfordsville; Dr. Otis B. Nesbit, Valparaiso; Mrs. E. W. Shirk, Peru; Dr. Eric A. Crull, Fort Wayne, and Dr. James A. Snapp, Goshen.

Personal.—Dr. Arvine E. Mazingo of the house staff of the Methodist Episcopal Hospital, Indianapolis, has been appointed to a similar position at the Metropolitan Hospital, Blackwell's Island, New York.—Dr. Darmon A. Rhinehart, instructor in anatomy in the Indiana University School of Medicine, Bloomington, has been appointed director of the anatomical department of the University of Arkansas, Little Rock.—Dr. Gilbert R. Finch, Center Point, was seriously injured by the overturning of his automobile, August 14.—Dr. Charles P. Hutchins, director of physical education at the Indiana University, Bloomington, has resigned and will practice in Rochester, N. Y.—Dr. Charles C. Morris, Rockville, has resigned the presidency of the Parke County Society for the Prevention of Tuberculosis.—Dr. Arnold Utterback, New Goshen, was painfully injured in an automobile accident, August 11.—Dr. Cassius E. Van Matre, Newcastle, is reported to be seriously ill with heart disease at his home.—Dr. Andrew W. Smith, Hammond, has been appointed director of athletics in Throop College, Pasadena, Cal.

KENTUCKY

Home from Europe.—Drs. John L. Phythian, Newport and John R. Murnan, Covington, reached home from Europe August 12.

Progress of Hookworm Campaign.—The State Board of Health reports that in the countries in which intensive health campaigns have been conducted under the auspices of the Board the doctors are on the lookout for intestinal parasites. They are certain that hookworm infection makes it practically impossible for the chronic diseases to get well on account of the decreased blood-supply. Of especial interest is the almost universal observation that, if uncinaria is diagnosed within the first few weeks of its first attack, except in the very severe cases, the patient usually recovers if promptly treated with thymol and this treatment is repeated at intervals of ten days until results are secured. Up to Jan. 1, last, the physicians of the state had reported the treatment of 45,470 cases of hookworm disease.

LOUISIANA

Lepers Discovered.—Four lepers were discovered in an isolated part of Arcadia Parish by Dr. Hines C. Webb recently and the unfortunate patients were sent to the State Leprosarium, White Castle.

Home from Europe.—Drs. Samuel M. D. Clark, Felix A. LaRue and Charles A. Borey, New Orleans, have returned from abroad.—Drs. Charles L. Chassaingnac, C. Jeff Miller, Gustav Mann and Otto Joachim, New Orleans, are reported to be still abroad.

Personal.—Dr. Andrew G. Friedrichs, for many years dean of the dental department of Tulane University, New Orleans, has resigned and has been succeeded by Dr. Wallace Wood, Jr.—Dr. Marcus J. Magruder, New Orleans, has been appointed a member of the board of administration of the Tulane University.—Dr. Joseph Conn, New Orleans, who was a passenger on the *Kronprinzessin Cecilie* on her memorable voyage, which ended at Bar Harbor, Maine, is sojourning at Clifton Springs, N. Y.—Dr. Isadore Dyer, dean of the Tulane Medical School, is taking a trip to Havana, Cuba.—Dr. Oscar Dowling, New Orleans, has been appointed chairman of the committee on vital resources of the National Conservation Congress.

Results of Hookworm Canvass and Campaign.—Dr. Sidney D. Porter, state director of the hookworm commission, has

issued a report of the two weeks' campaign in Tangipahoa Parish and the survey of the parishes of St. Helena, Washington, Livingston and St. Tammany. In the latter four parishes 5,397 microscopic examinations were made, and 52 per cent. found infected. In Tangipahoa 1,128 examinations were made, and 51.3 were found infected. In the preliminary campaign in the parish 1,228 patients were treated. No doubt is felt that insanitary conditions have caused the reinfection of many patients treated in the campaign three years ago. Since the inauguration of work in the state, 49 parishes have been surveyed and free dispensaries operated in 43, which has resulted in the treatment of 47,614 cases.

MASSACHUSETTS

Physicians Abroad.—Drs. Rufus A. Kingman and Calvin B. Faunce, Boston, have been detained in Europe by reason of the war.

Home from Europe.—Dr. and Mrs. Frank C. Granger, Randolph, Dr. George L. Richards, Fall River, and Dr. Fred B. Lund, Boston, have returned from Europe.

Physician Donates House for Hospital.—Dr. Charles S. Holden, Attleboro, has donated a summer home near Norton with the stipulation that it be used for a tuberculosis hospital for Attleboro.

Personal.—Drs. Sarah E. Coppinger, Needham Heights, and Thomas J. Scanlan, Boston, are the medical members of the board named by the governor to take charge of the Foxboro Hospital since its separation from the Norfolk State Hospital. At the first meeting of the board, Dr. Coppinger was elected secretary.—Dr. Charles F. McCaffrey, Somerville, has been appointed medical examiner of Middlesex County.

MINNESOTA

Home from Abroad.—Drs. Edwin Moren, Olaf J. Veline and Arthur E. Benjamin, Minneapolis; Dr. Louis A. Fritsche, New Ulm, Dr. Alfred E. Comstock, St. Paul and Dr. and Mrs. Edward W. Humphrey, Moorehead, have returned from abroad.

Minnesota Physicians Abroad.—Dr. and Mrs. Theodore L. Chapman and Dr. and Mrs. Robert Graham, Duluth; Dr. and Mrs. James L. Lynch, Winona, and Dr. John W. Lee, Minneapolis, are reported to be detained in Europe on account of war conditions.

Personal.—Dr. Thomas C. Clark, Stillwater, has been appointed chief surgeon of the Minnesota Soldiers' Home, Minnehaha Falls.—Dr. Arthur E. Benjamin has been appointed a member of the Minneapolis Board of Charities and Corrections.—Dr. William E. Harwood, Eveleth, has disposed of his hospital and will practice at his former home in Joliet, Ill.

Alleged Neglect in State Hospital.—On the recommendation of Dr. Henry M. Bracken, secretary of the State Board of Health, the governor has ordered an investigation of the State Hospital, Hastings, by the State Board of Visitors. Dr. Bracken's recommendation is said to be due to the failure of the hospital authorities to report cases of tuberculosis in the institution, although there were sixteen deaths from this cause in 1913, and there have been six deaths already this year from the same cause.

Southern Minnesota Physicians hold Summer Meeting.—The third summer meeting of the Southern Minnesota Medical Association was held in Winona, August 20 to 21 under the presidency of Dr. H. F. McGaughey. On the first evening, the association was entertained at dinner by the Winona County Medical Society and the medical profession of Winona. At this function, one hundred and thirty were present. At the first session, held after the banquet, Dr. William J. Mayo, Rochester, delivered an address on the "Influence of European Surgeons on American Practice" and Dr. Henry M. Bracken, Secretary of the State Board of Health, read a paper on preventive medicine. On the second day, a large number of papers were read and after luncheon, the members of the association were the guests of Drs. William J. and Charles H. Mayo, for an excursion on the steamer *Oronoco*. During the river trip, a session of the society was held.

Sanatorium Notes.—Representatives of Lincoln, Lyon, Pipestone, Murray, Cottonwood, Rock and Nobles counties, met in Tracy, August 8 to consider the establishment of a joint county tuberculosis sanatorium. A committee was appointed to examine three proposed sites, one at Lake Shatek, one near Windom and a third near Werthington.

MEDICAL NEWS

791

Plans are being prepared for the Clay-Becker County Tuberculosis Sanatorium at Sand Beach Lake. The building is to cost \$25,000 and an additional sum of \$10,000 will be appropriated for the equipment of the heating plant, lighting system, etc.—A sanatorium is to be erected by Beltrami, Hubbard and Koochiching counties, to cost \$35,000; the building is to be erected at Bass Lake and the governing board is composed of seven members, three from Beltrami and two each from the other two counties.—Dr. Albert J. Chesley, Minneapolis, epidemiologist for the City State Board of Health has commenced a campaign of education and arguments to influence the county commissioners to take advantage of the state law for the erection of city-county tuberculosis sanatoriums.—It is announced that Goodhue County will erect a tuberculosis sanatorium on the shores of Lake Billsby, near Canon Falls.—The work on the sanatorium which was to have been built in Crookston, has been suspended because of the failure of the county commissioners of Polk County to make the one-mill levy, and the withdrawal of Norman County from the agreement.

Sedlacek, Omaha, has been appointed vice-chairman of the State Prison and Parole Boards.—Dr. Joseph F. Borghoff, Omaha, has been appointed a member of the staff of the St. Francis' Hospital, Butte, Mont.—Dr. George Tilden, formerly years head of the Douglas County Commission, has resigned and has been succeeded by Dr. Samuel K. Spalding.—Dr. Adam R. Ray, who has purchased a ranch near Brownlee, and is about to leave Fairfield, was the guest of honor at a dinner given recently by the Clay County Medical Association.

NEW YORK

New York Physicians Abroad.—Dr. and Mrs. Grant C. Madill and daughter, Ogdensburg, and Dr. Jane N. Baldwin, Poughkeepsie, are in London awaiting opportunity for passage to this country.

Personal.—Dr. Howard L. Van Winkle, Syracuse, is first on the list of eligibles to be certified by the State Civil Service Commission for permanent appointment as bacteriologist of Onondaga County.—Dr. C. Grace Carroll, who is temporarily filling the position, also passed the examination for this position.

The Carmody Drug Decision.—In an opinion handed down on August 19, Attorney General Carmody holds that the name of the physical purchaser of a habit-forming drug and not the person for whose use it is intended must be taken at the place of sale. He also states that a physician must not only write out a prescription when administering, but must do so when dispensing a habit-forming drug.

Course in Hygiene and Preventive Medicine.—Albany Medical College announces a special course in hygiene and preventive medicine which shall have special reference to the needs of the general practitioner, and in addition the State Department of Health has consented to deliver a series of twenty lectures on subjects related to hygiene and preventive medicine, especially on the relation of bacteriology to public health and the control of communicable disease. The special lecturers announced are Drs. Hermann M. Biggs, Linsly R. Williams, Augustus B. Wadsworth, Cressy L. Wilbur and C. E. A. Winslow.

New York City

Return from Europe.—Drs. Adolph Rostenberg and George David Stewart, Dr. Morris Manges, Dr. and Mrs. E. J. Bissell, Dr. and Mrs. Charles N. Dowd and Dr. Henry W. Frauenthal and Alfred A. Herzfeld have returned from Europe.

Typhoid on Hart's Island.—On August 12 a case of typhoid fever appeared in the workhouse on Hart's Island and on the 21st it is reported that there are twelve cases in the workhouse and two in the reformatory. The island has been isolated by order of the Board of Health and no prisoners will be permitted to leave for the present.

Physical Tests in the Health Department.—As attesting the good faith of his conviction that regular periodic physical examination of all employees is both practicable and advantageous, Dr. Sigmund S. Goldwater has himself submitted to a physical examination as have also 300 employees of the Health Department. Of this number 95 were found to have physical defects of more or less serious nature. It is believed that about the same proportion will be found to exist in any other body of employees.

OHIO

Home from Abroad.—Dr. John V. Gallagher, wife and four children, Cleveland, and Dr. and Mrs. Birt E. Garver, Loraine, have returned from Europe.

Bureau of Child Hygiene for Cleveland.—Dr. Clyde E. Ford, commissioner of public health, has asked for an appropriation of \$11,400 to establish a bureau of child hygiene, and has asked for a total increase of \$23,000 in his annual appropriation.

Trachoma.—The eye hospital in East Youngstown, started by Miss Mary Runyan and Mr. J. Clyde Campbell, is continuing to treat a number of trachoma cases which have been occurring in the various industrial plants of the city of Youngstown. The results so far have been good.

Antismall-pox Campaign at East Youngstown.—Vigorous measures are being taken in East Youngstown to combat the spread of small-pox. Every pupil will be vaccinated as soon as school reopens. The health officer, Dr. Amos B. Sherk, declares there is little real opposition to vaccination among the people.

MISSISSIPPI

Vaccines and Antitoxins.—At a recent meeting of the State Board of Health, it was voted to procure a supply of vaccines, antitoxins and serums to be distributed to the public at cost.

Personal.—Dr. Edward C. Parker, Gulfport, has returned from Europe.—Dr. L. S. Rogers, West, will take charge of the State Charity Hospital, Jackson, about September 1.—Dr. Edward R. Cook, Vicksburg, charged with manslaughter in connection with the death of Miss Rosa Grant, was executed July 25.—Dr. Rives A. Manker, Long Beach, has been adjudged insane and committed to the State Hospital.—Dr. Noel C. Womack, Jackson, has been appointed a member of the State Board of Health, vice Dr. Giles S. Bryan, Armory, resigned.

MISSOURI

City Rents Isolation Hospital.—The city of St. Joseph has rented at a cost of \$60 a month, the sanatorium of Dr. William L. Wittington at Twenty-Third and Sacramento Sts. The institution is to be used as an emergency hospital for communicable diseases.

From, to, and in Europe.—Dr. Clarence B. Francisco and Dr. Jabez N. Jackson, wife and daughter, Kansas City; Drs. Floyd H. Spencer, Joseph J. Bansch and Louis J. Dandurant, St. Joseph, have returned from Europe.—Dr. Alex Van Ravenswaay, Boonville, has returned to Holland for war service.—Dr. Evan S. Connell, J. Elliott Royer, Albert J. Welch and Joseph E. Sawtell, Kansas City, are awaiting an opportunity to sail for the United States.

St. Louis

Personal.—Dr. Keating Baudoy is reported to be ill in the State Hospital from an overdose of paraldehyde.—Drs. John F. Gallagher and R. Lee Dorsett have been appointed assistant police surgeons.

In and from Europe.—Drs. James C. Whitley, Harriet H. Stevens and Lionel S. Luton are detained in Europe on account of the war.—Drs. Frank Ring and Joseph L. Emil and Julius Boehm have returned from Europe.

Lung Clinic Open.—A clinic for diseases of the lungs has been established at St. Marys Dispensary, by the St. Louis Society for the Relief and Prevention of Tuberculosis and the St. Louis University. The clinic is in charge of Dr. Andrew C. Henske and is open from 12 to 1 o'clock on Mondays, Wednesdays and Fridays.

NEBRASKA

The State Association Meeting.—Dr. Joseph M. Aiken, Omaha, secretary of the Nebraska State Medical Association, announces that the next annual meeting will be held in Hastings, May 18-20, 1915.

Nebraskans in Europe.—Dr. Oscar S. Hoffman and wife, Omaha, reached London August 4.—Drs. George A. Stevens, Frank M. Conlin, William N. Anderson, Joseph M. Shramek, Omaha, who reached Paris on their way to Vienna, sailed from Liverpool for this country, August 15.—Dr. E. Willard Powell, Omaha, has returned from Europe.—Dr. Palmer Findlay, Omaha, sailed for home, August 23.

Personal.—Dr. E. Dolphus Haysmer, Washington, D. C., has accepted the position of surgeon and superintendent of the Nebraska Sanitarium, Hastings.—Dr. Frederick A.

Public Health Nurses.—Miss Bertha Bronson has been appointed public health nurse to the city of Lorain. Funds for this purpose were furnished by the city council.—Akron is to have a public health nurse, who will also act as health inspector. The expense will be borne by the Summit County Health Protective Society.

Public Health League Membership Increases.—A recent campaign and canvass started by the Urbana Public Health League resulted in the enrollment of 350 members. The total membership has now reached 554. Many organizations and lodges have sought membership and Urbana factories and stores are giving the league their moral and financial support.

Condemns City Prison.—The Board of Health of Circleville had declared the city prison unfit for use on many occasions because of unsanitary conditions therein, but nothing had been done to remedy the conditions. Finally, at its last meeting, the board prohibited the use of the prison. There are many other such prisons in Ohio requiring action by boards of health.

State Board Laboratory Moves to University.—In furtherance of Secretary E. F. McCampbell's plan to promote closer cooperation between the various state departments and the state university, the laboratory of the State Board of Health will occupy one of the buildings on the campus, at present being remodeled for its use. The laboratory, now situated in the Hartman Building, is being dismantled and set up in a building formerly used by the botany department at the university.

Personal.—Dr. William C. Mendenhall, Trotwood, who was struck by an electric car at Crown Point, August 13, is reported to be in a serious condition at St. Elizabeth's Hospital, Dayton.—The office of Dr. Eugene C. Beam, Columbus, was destroyed by fire, August 4.—Dr. Millard F. Hussey, Sidney, has been reappointed a member of the board of trustees of the Lima State Hospital.—Dr. Ernest Crockett, Ashtabula, has been elected coroner of Ashtabula County, vice Dr. Robert J. Baxter, Conneaut, resigned to become postmaster of the city.—Dr. Fremont M. Marshall, for three years health officer of Coshocton, has resigned.

PENNSYLVANIA

Personal.—Dr. Henry B. Burns has been appointed head of the department of school hygiene of Pittsburgh.—Dr. Wallace R. Hunter, Erie, has been reappointed trustee of the Warren State Hospital.—Dr. and Mrs. Schaffer, Allentown, have returned from Europe.

Reading Infant Mortality Reduced.—Through the efforts of the Visiting Nurses' Association of Reading, the mortality rate among infants in that city has been greatly lowered. The Fresh Air Home for Babies at Antietam, a few miles below the city and one of the many baby saving stations conducted by the association, has done much toward reducing the number of deaths of infants. Already more babies have been treated than last year when the total number in the care of the association reached 150.

Philadelphia

Hospital Superintendent Dies.—Rev. William Service Steen, for sixteen years superintendent of the Presbyterian Hospital, died August 12.

Care of Babies to Be Part of School Curriculum.—At the last meeting of the Board of Education, a motion was passed which made the teaching of methods to be employed in the care of babies a regular part of the work to be followed in the domestic economy course in the elementary schools. This subject will hereafter be taught in nine of the present housekeeping centers of the public schools and if successful the course will be extended throughout all grades of the elementary schools.

Personal.—Dr. Walter L. Pyle has sailed for South America.—Dr. William L. Rodman has returned from Europe and a number of others are reported to be on their way, among them Dr. E. E. Montgomery, on the *Adriatic*, which left Queenstown, August 21, and Dr. John H. Girvin, on the *Olympic*, which sailed from Liverpool, August 22.—Dr. Constantino N. Ciafardini, who has just returned from Italy, was the guest of honor at dinner given by his fellow countrymen of this city August 21.—Dr. Karl Schaffle of this city has been appointed deputy medical inspector of tuberculosis dispensaries succeeding Dr. Edward B. Shellenberger, Warren, resigned.—Dr. John E. B. Buckenham has been

appointed acting chief resident physician at the Hospital for Contagious Diseases during the absence of Dr. Samuel S. Woody on vacation.

VIRGINIA

Home from Abroad.—Drs. Israel Brown, W. Levi Old and Starke A. Sutton, Norfolk, have returned from Europe.

The Care of Infants.—The State Board of Health has issued 40,000 pamphlets on the care of infants, illustrated by photographs containing detailed directions for the care of infants and the general principles for the modification of milk.

State Health Board Appointments.—The governor has announced the following reappointments to the State Board of Health: first district, Dr. Samuel W. Hobson, Newport News; second district, Dr. Otto C. Wight, Jarratt; eighth district, Dr. William M. Smith, Alexandria.

Personal.—Dr. J. O. Fitzgerald has been elected bacteriologist to the State Board of Health with Dr. Gray as his assistant.—Drs. Charles M. Labenberg, Charles V. Carrington and Ramon D. Carcin have been appointed the new board of pension examining surgeons of Richmond.

Bacteriologist to Resign.—Mr. Aubrey H. Straus, for five years bacteriologist of Richmond, has announced that he will leave the service of the city at the end of the summer to become associate professor of bacteriology and preventive medicine in the University of Virginia, Charlottesville.

WISCONSIN

Sanatorium Plans Approved.—Plans for the Winnebago County Tuberculosis Sanatorium have been approved and advertisements for bids have been made.

New Health Insignia.—The city ambulance of Racine is now decorated by a gold star within a blue circle instead of the red cross which formerly designated the character of its work.

Detained in Europe.—Drs. John M. Dodd, Ashland; Charles W. Giesen, Superior; John Durner, Milwaukee, and Flora A. Read, Fond du Lac, are believed to be detained in Europe on account of war conditions.

Home from Abroad.—Drs. Thomas W. Nuzum and Edmund F. Woods, Janesville, have returned from Europe.—Dr. Albert M. Farrell, Two Rivers, reached New York, August 16.—Dr. Frederick A. Kraft, Milwaukee, returned from Europe, August 10.

Personal.—Dr. John W. Coon, Milwaukee, formerly superintendent of the City Tuberculosis Hospital, Wales, has been appointed superintendent of the new Municipal Tuberculosis Hospital, Chicago. Dr. Glenford L. Bellis, Wales, obtained the highest mark of the Cook County Civil Service examination, July 29, for health physicians at the Cook County Tuberculosis Hospital, Oak Forest.

GENERAL

Eye, Ear and Throat Specialists to Meet.—The annual meeting of the American Academy of Ophthalmology and Oto-Laryngology will be held in Boston, October 19 to 21.

Red Cross Offers Services.—The American National Red Cross has decided to offer its services to all nations involved in the European war. The secretary is at present in Europe and the international relief board is considering ways and means of rendering service. Ten hospital units each consisting of three surgeons and twelve nurses with complete equipment are said to be now ready to be sent to the European war zone.

The Plague at New Orleans.—Since the last report, two cases of provisional diagnosis, bacteriologically confirmed, of bubonic plague, have been made in the following cases: Case 18, Ching Sam, Mongolian, male, aged 72, residence, 911 Toulouse St., employed at the Chinese Restaurant, 916 Toulouse St., sick four or five days, found dead Aug. 16, 1914, diagnosis, septicemic plague. Case 19, Mary Hooper, colored, female, aged 40, residence, 1905 Bienville St., sickened August 14, removed to Isolation Hospital August 16, with right femoral bubo. Case 20, Louise Welsh (daughter of Mary Hooper), colored, female, aged 24, residence, 1905 Bienville St., sickened August 16 with left femoral bubo, removed to Isolation Hospital. Cases 55 to 64 of rodent plague have been reported up to August 22. During the week ended August 15, 101 vessels were fumigated; 12,705 pounds of sulphur were burned; 12,304 tons of outgoing freight were inspected; 21 clean bills of health and 7 foul bills of

health were issued in the outgoing quarantine department. In the department of overland freight inspection, 6,510 cars were inspected, 1,403 cars were rat-proofed, 5 cars were condemned and one rodent was killed in a car. The field operations for the week included 10,202 rats trapped; 33 premises fumigated; 57,955 poisons placed; 4,366 premises inspected; 1,624 notices served; 1,449 abatements and 117 dead inspected. At the laboratory 10,351 rodents were received and 9,001 examined. Of the rats, 37 were suspicious and in 17, the diagnosis of plague was confirmed. Since July 8, 44,135 rats have been examined.

CANADA

Canadian Surgeons for the Front.—While no official list of the Canadian Medical men attached to the militia has been published, it is understood that amongst others the following will be in the first Canadian contingent: Lt.-Colonel Duff in command; Dr. John L. Chabot, M.P., Ottawa; Hon. Dr. Henri S. Beland, N. Joseph, Que. and Drs. Perry G. Goldsmith and J. Harvey Todd, Toronto.

Infant Mortality in Canada.—With a little less than one-sixth the population of New York, Montreal heads the list in Canada in infant mortality. It has three times the mortality per 1,000 that New York has. Recent statistics places it at 290 per 1,000 births. Brandon comes next with 269; Ottawa, 256; Winnipeg, 169; Hamilton, 173; Halifax, 204; London, 164. By provinces the deaths per 1,000 births are as follows: Manitoba, 149; Ontario, 131; Saskatchewan, 130; Nova Scotia, 111; Prince Edward Island, 104. It is surprising to see the new western cities heading the list.

Hospital News.—The Vancouver General Hospital which has for the past seven years expended at least \$5,000 a year in the treatment of Hindus will make an attempt to collect this amount from some Hindu leader in that community, since the Hindus were able to raise \$14,000 to pay charter money for the steamer *Komagata Maru*.—The new St. Justine Hospital for Children was recently opened in Montreal. It contains eighty beds, three public wards, one private ward and a dispensary.—An Industrial Home for the Blind is in course of erection at Notre Dame de Grace, Montreal.—The Union National Française, Montreal, is to build a hospital at Maisonneuve.—The Bruchesi Institute at Montreal in 1913-1914 had 3,285 patients attend its clinics, the total number of consultations being 14,042. The number of deaths from tuberculosis registered in Montreal for that fiscal year was 1,083.

Health Items.—The death-rate in Toronto from typhoid fever in 1913 was 10.4 per 100,000 of the population. If the cases contracted outside the city were deducted, the rate would stand at 5.3. This would be the lowest rate of any American city, with a population over 350,000, outside of New York. In 1910 the death-rate stood at 40.8.—The new addition to the Toronto filtration plant on the Island is to have a capacity of 60 million gallons. It is to be of the mechanical type known as the Ver Merh drifting sand filter. Toronto will be the first city of large size to install this system and it is expected to be one of the finest and most modern filtration plants in the world.—The Department of Health, Toronto, has made a thorough survey of all factories and industries in that city—1,294 in all. In 80 per cent. the conditions are fairly good, but in the remaining 20 per cent. the conditions were such as to call for immediate action on the part of the Department.

Nova Scotia Provincial Sanatorium.—The Nova Scotia Government established the Provincial Sanatorium at Kentville in 1904. The ninth annual report of the medical superintendent, Dr. A. F. Miller, states that during the year ended Oct. 31, 1913, there were sixty-four applications for admission and that of these thirty-eight were accepted. At discharge twenty-three of these were apparently cured, eleven arrested, two improved, whilst two only failed to respond to treatment. It has been found that when tuberculin is used patients do better while in the sanatorium, but little ultimate benefit is apparent. Accurate records of all patients have been kept since January, 1910. Since that time ninety-four patients have been received for treatment. Fifty-nine of these are now well and working; nineteen are not working; fifteen are dead; the condition of only one remains unknown. There is great need in the province for hospitals for needy patients. A weekly fee of five dollars is charged and the balance for maintenance is supplied by the Government.

Infant Mortality in Toronto.—In June the Department of Health inaugurated a new branch of its service, known as the

Division of Child Hygiene with Drs. Alan Brown and George Campbell in charge. The appointments are in the hands of the professor of pediatrics in the University of Toronto and the Medical Officer of Health. Toronto now has a population of 510,000 of which 10,960 are under one year of age and 21,070 under two years. In 1897 the infant mortality totalled 664 when the population stood at 197,000. During the last five years it has been as follows: commencing with 1909—1,410; 1,420; 1,432; 1,584; 1,877. To care for the children in times of sickness there are the Hospital for Sick Children with 250 beds—baby wards, thirty cots. It has its own pasteurizing plant and supplies seven milk depots. The Infants' Home cared last year for 289, of whom 76 died during the year. St. Vincent's Home has an average of 100 cases in residence. The Haven, 61—nine died; The Sacred Heart Orphanage, inmates, 200. There are forty-two licensed baby farms. There are eight day nurseries, and numerous private organizations working for the infants. A floating sanatorium provides trips for about three hundred mothers and babies. The well-baby clinics number ten which will be increased to twenty-five in 1915.

LONDON LETTER

LONDON, Aug. 7, 1914.

The War: Medical Service

The greatest war which the world has ever seen has broken out suddenly and unexpectedly, yet there is every reason to think that the medical service of this country will be quite adequate for the work. Before the declaration, the navy, including its medical service, was completely mobilized. The medical officers of the reserve were called from their civilian duties. A number of surgeons have also been engaged for temporary service and senior students to act as dressers. Trained nurses have been called from a reserve organized by the matrons of the large hospitals for service in the naval base hospitals. Expert surgeons and anesthetists from the large hospitals are ready for duty as soon as the sick and wounded are landed from the hospital ships.

For the territorial force of the army, physicians have been called from civilian practice. Fourteen mounted brigade field ambulances, forty-two field ambulances and twenty-three general hospitals are available. Civilian physicians have responded to the call for service at home and abroad as temporary surgeons. Many private citizens have offered their residences for use as hospitals or convalescent homes.

THE CLINICAL CONGRESS OF THE SURGEONS OF NORTH AMERICA

(Concluded from page 697)

The Selection of Operation in the Treatment of Gastric and Duodenal Ulcers

Dr. A. von Eiselsberg said that symptoms of perforation of the ulcer into the general peritoneal cavity call for immediate operation, irrigation of the peritoneal cavity, closure of the perforation and in bad cases jejunostomy in addition for the purpose of administering nourishment. In the other complications of ulcer, such as hemorrhage, operation is in most cases better not done. In typical stenosis of the pylorus, especially when in the case of a long-standing ulcer no new symptoms have occurred, gastro-enterostomy is the operation to be chosen. Unilateral pylorus exclusion offers the greatest security in ulcer and its complications. For ulcer situated at a distance from the pylorus simple gastro-enterostomy is not so feasible as in cases of ulcer of the pylorus itself.

Hyperthyroidism

Dr. C. H. Mayo, Rochester, Minn., said that exophthalmic goiter is essentially a disease of a chronic character, presenting exacerbations and ameliorations of symptoms extending over a period of months or several years. The operative interference in cases resistant to treatment should be confined to injections of boiling water into the gland after Porter's plan to hasten improvement. In most of the severe cases a ligation is made first of the left upper pole only. Should the reaction following this be severe, the ligation of the right upper pole is indicated a week later, and thyroidectomy reserved until four months have elapsed, by which time these patients have made an average gain of 22 pounds, with great general improvement. However, if the reaction following the left ligation is not unduly severe, a partial thyroidectomy may be made at the second operation, the week following.

Typhoid Perforation

Dr. G. E. Armstrong, Montreal, pointed out the great difficulty in diagnosing. The first indication was usually pain, but it was absent in 25 per cent. of the cases. The symptom next in importance was change of expression, which was quite evident in the majority of the cases; 65 per cent. showed a definite alteration, 28 per cent. showed a gradual one, and 7 per cent. none. Tenderness was present in 88 per cent. and absent in 12. Rigidity was distinct in 85 per cent. and not in 15.

The Non-Operative Treatment of Carcinoma

Krönig of Freiburg was to have read a paper on this subject, but was recalled by the war. Dr. C. Jeff. Miller of New Orleans therefore gave his impressions of a visit to Krönig's clinic. He asked Krönig whether he was in favor of radiation treatment for early operable uterine tumors as well as for advanced cases, and was told that operation had been given up entirely. Roentgen-ray treatment was regarded as superior to hysterectomy for fibroids, though in women under 40 myomectomy was performed when feasible. Contrary to Bumm's statement that deep-seated tumors cannot be influenced by the Roentgen ray, Krönig believes that cancer of the stomach can be made to cicatrize, and even when there are secondary growths in the liver, retrogression can be brought about. Radium and thorium in large doses are also much employed by Krönig. He holds that large doses of radium strongly filtered have great possibilities in malignant disease in deep-seated organs. He uses large quantities of radium and thorium applied at a distance. For carcinoma of the cervix he does not apply radium through the vagina but from outside the abdomen. He does not believe in the implantation of radium into growths. Summing up, Dr. Miller said he was impressed by what he saw, but not convinced.

Dr. T. W. Eden of London admitted that the Roentgen rays were useful, but was less certain about radium. By the former a very beneficial effect may be produced though the disease may be advancing in the deeper tissues. The best promise of improved results is in the Roentgen rays combined with operation.

Mr. W. E. Miles of London never used radiant treatment but confined himself to operation. It is necessary to remove not only the organ affected but also the tissues through which spread has taken place and through which it will take place. In operating for uterine cancer the interiliac glands should always be removed whether obviously affected or not. If found infiltrated, the iliac glands should also be removed.

Dr. Joseph Bloodgood of Baltimore said that surgeons were so overwhelmed with the details of technic of extensive operations that they had not given sufficient attention to the beginnings of cancer. Cancer always gave warnings to its subjects and therefore a campaign of education should be undertaken. At the stage at which cases should be treated the mortality should be practically nil. Preventive treatment is all important, for cancer never develops in a healthy spot.

Marriages

LUCIUS P. BECK, M.D., Piedras Negras, Mex., to Miss Minnie E. Stephens of San Antonio, Tex., at Uvalde, Tex., August 3.

ISAIAH E. LAWRENCE, M.D., to Miss Grace Vivian Coyle, both of Columbia City, Ind., at Detroit, Mich., August 11.

GEORGE CHAUNCEY WRIGLEY, JR., M.D., to Miss Marie A. Timm, both of Dixon, Cal., August 8, in Sacramento, Cal.

JOSEPH DANIEL HEITGER, M.D., Bedford, Ind., to Miss Katherine Georgina Everbach of Louisville, Ky., July 15.

EDWARD LEWIS TEED, M.D., Lis'le, N. Y., to Miss Nettie Knoeller of Hallstead, Pa., at Syracuse, N. Y., August 6.

WILLIAM DEHART FITZHUGH, M.D., Doe Hill, Va., to Miss Bessie May Wagner of Monterey, Va., June 30.

RALPH HOMER BOICE, M.D., to Miss Mabel Chatterdon, both of Sistersville, W. Va., August 12.

JOHN ROBERT WHITE, M.D., Lynn, Mass., to Miss Margaret E. Hale of New Haven, Conn., July 21.

JOSEPH HAROLD FRIEDMAN, M.D., to Miss Sarah Margulies, both of Brooklyn, N. Y., August 9.

Deaths

Eugene Alfred Smith, M.D. University of Buffalo, N. Y., 1887; a Fellow of the American Medical Association; adjunct professor of clinical surgery in his Alma Mater; attending surgeon at Buffalo Hospital and assistant at Charity Hospital; consulting surgeon to the German Deaconess, Riverside and Woman's hospitals; once major and surgeon of the 65th Infantry, N. G., N. Y.; for many years a practitioner of Buffalo; died at his home in Saranac Lake, N. Y., August 9, from tuberculosis, aged 49.

William G. Ralston, M.D. Medical College of Evansville, Ind., 1873; a practitioner of Indiana since 1845; surgeon of the Eighty-First Indiana Volunteer Infantry and later secretary of the enrollment board of the First Indiana District during the Civil War; later surgeon of the U. S. Marine Hospital at Evansville; a member of the Mississippi Valley Medical Association; said to have been the oldest practitioner of Indiana; died at his home in Evansville, August 11, aged 95.

Wesley Harris Sharp, M.D. University of Pennsylvania, Philadelphia, 1865; a Fellow of the American Medical Association and a charter member of the West Virginia State Medical Society; hospital steward in the Navy during the Civil War; one of the oldest and most respected physicians of West Virginia; died at his home in Parkersburg, August 5, from uremia, aged 71.

Edgar B. Smith, M.D. Detroit College of Medicine, 1887; a Fellow of the American Medical Association; professor of surgery in the Michigan College of Medicine and Surgery, Detroit; surgeon in chief of the Boulevard Sanitarium, Detroit; died at his home, August 11, from septicemia due to an operation wound received three weeks before, aged 52.

Wallace B. Amick, M.D. Hospital College of Medicine, Louisville, Ky., 1898; of Glenalum, W. Va.; a Fellow of the American Medical Association; physician to the Glenalum Coal and Coke Co.; while traveling on a railway velocipede with the paymaster of the company; was shot and killed by robbers, August 14, aged 39.

Edward P. Childe (license, Nebraska, 1891); for fifty-three years, and until 1913 a practitioner of Nebraska; a veteran of the Sioux and Blackfeet campaigns; for one term a member of the Territorial Legislature of Nebraska; died at his home in Seattle, Wash., recently, after a surgical operation, aged 78.

William Andrew Forster, M.D. Homeopathic Medical College of Missouri, St. Louis, 1888; professor of surgery in the Kansas City Hahnemann Medical College; for twenty-five years a resident of Kansas City, Mo.; died in Grace Hospital in that city, August 8, after a surgical operation, aged 58.

Liston Homer Montgomery, M.D. Northwestern University Medical School, Chicago, 1871; a Fellow of the American Medical Association; a veteran of the Civil War; secretary of the Ohio Society of Chicago; died at his home in that city, August 24, from cerebral hemorrhage, aged 66.

John Lazelle Sawyers, M.D. Northwestern University Medical School, Chicago, 1878; of Centerville, Iowa; a Fellow of the American Medical Association; died in Augustana Hospital, Chicago, August 10, ten days after an operation for appendicitis, aged 58.

George G. Graham, M.D. College of Physicians and Surgeons, Baltimore, Md., 1882; formerly an alienist of Pittsburgh, and a member of the staff of Dixmont Hospital for the Insane; died at his home in Santa Barbara, Cal., August 9, from heart disease.

Nathan Cash, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1865; a veteran of the Civil War and for nearly forty years a practitioner of Uhrichsville, Ohio; died at his home in that city, August 12, from cerebral hemorrhage, aged 74.

James P. Cox, M.D. Northwestern University Medical School, Chicago, 1904; of Jefferson, Wis.; a member of the Wisconsin State Medical Society; died at St. Mary's Hospital, Milwaukee, August 12, after an operation for appendicitis, aged 38.

John C. Hallam, M.D. Marion-Sims College of Medicine, St. Louis, 1899; a Fellow of the American Medical Association; for several years a practitioner of St. Louis; died at his old home in Centralia, Ill., August 13, aged 38.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

The Radio-Activity of the Waters of Saratoga Springs

The article by Richard B. Moore and C. F. Wittemore (*Jour. Indust. and Engin. Chem.*, July, 1914, p. 552), quotations from which are given below, is of special interest in view of the general confusion of ideas with regard to radio-active waters. The work described was done by these authors for the Bureau of Mines at the request of the commissioners of the state reservation at Saratoga Springs, New York, in order to determine to what extent the waters and gases evolved from them were radio-active. THE JOURNAL comments on the work editorially elsewhere.

"The work done involved the direct testing of the gases evolved from the springs for thorium and radium emanation; the examination of the waters: (a) for their total activity; (b) of a certain number for the activity due to dissolved radium salts; and the determination of the activity of the residues deposited by the springs, where such residues could be obtained.

"The activity of any water may be due to the presence of (a) dissolved thorium or radium emanations, (b) dissolved thorium and radium salts. All mineral and deep well waters are more or less radio-active, but the activity is usually due to the presence of dissolved radium emanation, not to dissolved radium salts. Therefore, the fact that a water is radio-active has of itself little significance. . . . [Italics ours.—Ed.]

"Tests on the activity of the evolved gases were made on the ground in the following manner: A glass funnel to which was attached a rubber tube connecting with a small rubber bulb in turn connected with one of the openings to an electroscope, was inverted over the spring at a point where the evolution of gas was greatest. By pressing the bulb, a continuous and fairly constant supply of the gases from the spring was passed through the electroscope. By stopping the flow of gas and immediately making a series of readings across the scale, each reading being of short duration, it was possible to ascertain whether the activity was entirely due to the presence of radium emanation. If thorium emanation was present, a very sudden drop in activity would be noticed and, after a few minutes, the curve obtained by plotting activity against time would flatten out, due to the decay of the thorium emanation. In no case was thorium emanation found in any of the gases evolved from the springs, the activity being entirely due to the presence of radium emanation.

In order to get the activity of the waters, samples which previously had been collected at the springs at a point nearest to the source of supply, were boiled in the apparatus designed by Schlundt and Moore¹ and the evolved gases containing the radium emanation were introduced into a standardized electroscope. "On account of the large amount of carbon dioxide contained in some of the waters it was found advisable to add a sufficient amount of C.P. sodium hydroxid before boiling. In order to differentiate between the activity due to radium salts in solution and that due to dissolved emanation, samples of some of the waters were treated with C.P. hydrochloric acid, boiled for fifteen minutes and then sealed in flasks and allowed to stand for a month. At the end of this period they were boiled in the usual way and from activity obtained it was possible to calculate the amount of radium salts in solution.

"Samples of deposits from some of the springs were also collected and fused with sodium carbonate according to the method of Strutt.²

"Column 2 in the table of results gives the activity per liter at standard temperature and pressure, of the gases evolved by the springs; Column 3 gives the total activity per liter of the water, and Column 4 the activity per liter of the

water due to dissolved radium. Column 5 shows the activity of the material deposited either in or just around the outlet of the spring.

	Tempera- ture ° C	Gas Radium per Liter Gram $\times 10^{-11}$	Water Radium per Liter Gram $\times 10^{-11}$	Deposit Radium per gram Gram $\times 10^{-11}$	
Spring	1	2	3	4	5
Emperor	9.7	22.1	7.0	6.8	
Peerless	...	...	6.0	...	
New red	10.0	8.0	4.3	...	
Hathorn No. 1.....	10.2	21.3	14.2	4.2	76.9
Coesa	10.2	8.1	9.7	...	7.9

Island	...	...	11.8	...	10.5
Crystal Rock	10.0	84.7	88.0	0.9	
New Shouts well.....	...	...	11.3	...	

" . . . The fact that the residues are radio-active shows that the waters contain dissolved radium salts in addition to dissolved emanation, but this fact is more precisely indicated by the results under Column 4. . . .

"The total activity of the waters is rather low, although that of the Crystal Rock spring is considerably above the average. The activity of this spring, however, is not exceptional.

"Since these analyses were made, the hydrostatic level of the waters at Saratoga Springs has distinctly changed, owing to the cessation of the extensive pumping for commercial purposes which formerly took place. Accordingly, the flow of many of the wells has increased. Whether this has also affected the radio-activity of the water cannot be predicted with certainty."

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

WHAT CONSTITUTES FIRST AID?

To the Editor:—We are having a controversy with a liability company as to what constitutes first aid in fracture cases. We maintain that this includes the reposition of the fracture and the x-ray pictures necessary for its successful reduction. The liability company says that radiographs cannot be included in first aid. Our attorney tells us that there has been no ruling on that point in this state. Please tell us the ruling in Illinois or adjoining state or advise us in any other way on this point (What constitutes first aid?), as we are inclined to make a test case of this rather than accept the niggardly offer of the liability company.

T. J. BILLION, M.D., Sioux Falls, S. Dak.

ANSWER.—What constitutes "first aid" is a question of considerable importance owing to the great increase of accident and liability insurance. So far as we are aware no judicial decision has been handed down defining "first aid"; but a brief reference to the manner in which the term came into general use will aid one in arriving at a clear understanding of the scope of its meaning. When a person is accidentally injured or suddenly taken ill it is perfectly natural for those about him to render any aid or assistance within their knowledge and power. The humanitarian principle underlying such service has been long recognized and has inspired the formation of societies of laymen, the members of which receive a certain amount of instruction in order that they may be better able to render such service in an emergency. These societies are usually called first-aid societies, the idea being to give aid pending the arrival of a physician or surgeon.

The importance of doing something to relieve the injured, and particularly in the case of wounds to protect them from infection as much as possible, has caused most industries, railroads, etc., to provide first-aid outfits and to have certain of the men instructed in giving first aid until the patient can be turned over to a physician, or can be removed to a settled place such as his home or a hospital. There can be no question that the service thus rendered by laymen in such emergencies is "first aid"; but now suppose the one nearest at hand to the injured is a physician, or suppose that some one with no other authority than that of trying to do something to aid one in trouble summons a physician. Does the physician give "first aid," and if so, what is included in "first

THE SENSORY AND MOTOR DISORDERS OF THE HEART. Their Nature and Treatment. By Alexander Morison, M.D., F.R.C.P., Senior Physician to the Great Northern Central Hospital, London. Cloth. Price, \$2.50 net. Pp. 261, with 51 illustrations. New York: William Wood & Co., 1914.

This volume is an earnest and dignified effort to set forth the importance of considering the nervous mechanism of the heart when attempting to understand the working of this organ in health or disease. Morison believes that the myogenists have been overenthusiastic in their claims. Not only does the ordinary muscle of the heart show nervous structures, but such specialized areas as the sinu-auricular node, Tawara's node, the bundle of His, and the wall of the coronary arteries are rich in nervous tissue whose function must surely be reckoned with. He is also not convinced that the atrioventricular node and bundle are purely vestigial remains of embryonic tissue; he believes that they have participated in the progressive development of the heart, growing and exercising their own special functions. His study of angina pectoris has led him to the belief that its causes may be various. He refuses to commit himself to any single theory of angina pectoris. The condition of the blood, of the nerves, the vessels, the muscle, may all be contributing factors. In fact, he believes that in many instances there are operating several causes constituting a "compound angina pectoris." So he is able to agree with those who regard the cause of the stenocardiac attacks as due to coronary obstruction, coronary spasm of the heart-muscle and stretching of the muscle from dilatation, and with those also who regard the pain as neuritic, neuralgic, aortic, etc. His discussion of the prognosis and treatment is clear and sane. He is evidently not inclined to use digitalis in angina so freely as some others, who, it seems to us, are in the right. There is a brief consideration of some of the disturbances of cardiac rhythm. This gives Morison another opportunity to emphasize the importance of the nerve-control of the heart. He also reveals his skeptical attitude toward some of the more recent views in cardiology. For instance, he doubts the usual interpretation of auricular fibrillation. The tachy-arrhythmia of the ventricle may be the cause and not the effect of the perverted auricular action (pp. 182, 222, etc.). He discusses heart-block enough to let one know that he thinks there are some things about it that are not yet proved. Altogether the book is an interesting contribution to the literature of heart-disease. The results of Morison's clinical experience are here set forth as well as epitomes of numerous post-mortem examinations in instructive cases that he has studied during life. From each one of these cases the author tries to draw some lesson bearing on the anatomy, physiology or pathology of the heart, and such studies are always of value. Morison is—to use a political expression—a stand-patter, a reactionary. He fights shy of the electrocardiograph and interpretations based on it. The older methods are good enough for him. We enjoy his well-worded thrusts at the progressive cardiologist, and must acknowledge that some of them strike home; but at the same time we feel that the sum total of his criticism, sincere as it is, is rather in the direction of retarding than advancing a knowledge of the truth.

DIE LOKALISATION IM GROSSHIRN UND DER ABBAU DER FUNKTION DURCH KORTIKALE HERDE. Von Dr. Med. C. v. Monakow, Professor der Neurologie, Universität in Zürich. Paper. Price, 48 marks. Pp. 1033, with 270 illustrations. Wiesbaden: J. F. Bergmann, 1914.

In this book the author of the well-known classic on *Gehirnpathologie* gathers together his scattered writings on brain localization and functional disturbances caused by lesions of the brain cortex, and molds them into a homogeneous whole. We can safely predict that the book is destined to become a source of inspiration to all who are interested in any branch of neurologic science. The author begins with general remarks on the symptomatology of lesions in the brain cortex, and points out that the initial symptoms of a

lesion limited in extent are often entirely out of proportion to the amount of tissue involved, but seem to originate in centers remote from the seat of the lesion. This phenomenon as well as the gradual or rapid subsidence of many of the symptoms he believes to be due to the so-called process of "diaschisis," in support of which theory this book was written. By the term "diaschisis" Monakow means essentially "that shock-like cessation of function in nerve-centers widely separated in location but physiologically related in some manner and usually functioning synchronously with the center in which the lesion has occurred." He thus explains the multififormity of symptoms following a lesion in a known brain area and the gradual recession of many of the symptoms: diaschisis having passed off, there remain only the symptoms actually caused by the anatomic change in the brain. Monakow is thoroughly convinced that his theory will account not only for the many hitherto unexplained phenomena which follow a lesion of the brain, but also for the restitution of certain lost functions. He does not accept the assumption of "vicarious and compensatory action of parts of the brain not disabled for those unable to carry on their work." To him this theory is not supported by facts. Likewise he doubts the existence of strictly circumscribed physiologic brain territories. With the exception of the most elementary processes in the sensory sphere, there is to him a physiologic overlapping of most of the brain functions. In the subsequent chapters the author reviews the experimental and clinical work on the localization of motion, sensation and the special senses, as well as the interesting and yet obscure topics of agnosia, apraxia and aphasia. Everywhere he finds lacunae which only diaschisis is able to fill. Whether diaschisis is the true explanation and will cover the many hiatuses in our knowledge of cerebral localization, or whether some other theory will take its place, it is a pleasure to follow the author through a thousand pages of highly scientific and critically well-digested material. Monakow has again given to the profession a monumental work, the like of which is to be found in no other language; apart from its controversial character, it gives the best summary of cerebral localization with which we are acquainted. The bibliography alone contains 3,174 references.

THE PRACTICE OF PEDIATRICS. By Charles Gilmore Kerley, Professor of Diseases of Children in the New York Polyclinic Medical School and Hospital. Cloth. Price, \$6 net. Pp. 878, with 139 illustrations. Philadelphia: W. B. Saunders Company, 1914.

This book is not merely a new edition of Dr. Kerley's "Treatment of Diseases of Children"; it is a comprehensive text-book on diseases of children. Dr. Kerley's students will appreciate his book. In addition to being an excellent text-book, it has that direct personal appeal of the clinical teacher of large experience. The book is not simply a compilation, but every page reflects the personal opinion of the author. This makes it peculiarly positive and practical when coming from a clinician of such large and varied experience. The book can be recommended safely to the student, but even more to the practitioner, as a conservative, sane, up-to-date, practical treatise on pediatrics that easily takes its place among the two or three best American text-books on that subject. The chapter on vaccine therapy is up to date but conservative, and those especially interested in gymnastic therapeutics will find forty pages devoted to that subject.

IMMUNITY: METHODS OF DIAGNOSIS AND THERAPY AND THEIR PRACTICAL APPLICATION. By Dr. Julius Citron, Assistant at the University Clinic of Berlin. Translated from the German and Edited by A. L. Garbat, M.D., Assistant Pathologist, German Hospital. New York. Second Edition. Cloth. Price, \$3.50 net. Pp. 267, with 40 illustrations. Philadelphia: P. Blakiston's Son & Co., 1914.

This edition of Citron's well-known manual on immunity will undoubtedly prove even more popular than the first. The subject-matter has been brought thoroughly up-to-date through valuable additions made by the editor. In these days the subject of immunity and immunologic reactions has become so extensive that the general worker may hope for little beyond a slight knowledge of this field. Books like this

present the material in such a clear-cut and concise manner that the more important phases of the work may be grasped in a short time. Moreover, this book gives such attention to detail of technic that one may become qualified to perform the usual tests applied to such investigations. It is not to be supposed, however, that the mere mastering of technic will make a specialist in such work. Citron, as well as many others, emphasizes the fact that careful study of the variations arising in different tests as well as of the methods of proper control of all tests must be made before one is able to attempt the proper interpretation of his tests. Care and precision in each test made as well as an enormous experience along lines of serum diagnosis are necessary for the worker in this field. The subject-matter embraces both theoretical and practical discussions, the latter being limited to methods used in the clinic for diagnostic, therapeutic or prophylactic purposes. Citron's wide experience enables him to point out the various details of the tests so clearly that little excuse is given for improper technic. This book may be commended to the general and even special worker as, probably, the clearest and most practical exposition of this important field of research at our disposal.

LE LABORATOIRE DU PRACTICIEN. Analyse Clinique—Méthodes et Procédés. Guide de Diagnostic et D'Hygiène Prophylactique des Maladies Communes Exotiques et Tropicales. Par Paul Gaston, Chef du Laboratoire Central et de Radiologie de L'Hôpital Saint-Louis. Third Edition. Paper. Price, 4 francs. Pp. 140, with 319 illustrations. Paris: A. Poinat, 1914.

With the appearance of the third number, Gaston completes his admirable discussion of the value and limitations of the physician's laboratory. As Gaston has previously pointed out, the general worker should not only be in a position to perform a large portion of his own laboratory work but, especially, must also have sufficient knowledge of theory and technic to enable him properly to interpret the findings of others. The proper fittings and equipment as well as the more important methods to be used have been the points taken up in this little manual. This number deals, in a clear and concise manner, with the chemical and microscopic examination of the urine; study of colloids and crystalloids; investigation of normal and pathologic secretions and excretions; examination of feces; methods of histology and pathology, and serodiagnosis, especially as applied to the study of agglutination and complement fixation. It is not to be supposed that the methods have received extensive elaboration, as this is not the purpose of the work. Enough is given, however, to enable one to become familiar with the best methods of study of a given problem. The illustrations are numerous and, for the most part, adequate. This manual is to be commended to those who may wish a brief work covering the more important phases of the rather extensive and important field of clinical diagnosis.

PAIN: ITS ORIGIN, CONDUCTION, PERCEPTION AND DIAGNOSTIC SIGNIFICANCE. By Richard J. Behan, M.D. Cloth. Price, \$6. Pp. 920, with 191 illustrations. New York: D. Appleton & Co., 1914.

The first 140 pages of this book treat of pain in the abstract. Here the author discusses the perception, nature, distribution and intensity of pain and its relation to other sensations. He has made an exhaustive study of the literature on the related subjects from which he often quotes: He is somewhat dogmatic at times, but this makes the subject-matter clearer than if he expressed the conflicting views of the literature. The remainder and greater part of the book discusses the pains which are peculiar to special organs, as the appendix; and to special regions, as pains in the back or head. The author pays particular attention to differential diagnosis of pain and has a number of well-arranged tables on diagnosis. The value of the work is considerably enhanced by many excellent illustrations and diagnostic charts. The book should prove valuable to the general practitioner, both as a reference book for the particular case and for a careful study of the whole subject. There is a well-arranged bibliography whereby those who wish to consult the original literature may be able to do so.

LECTURES ON DIETETICS. By Max Einhorn, Professor of Medicine at the New York Post-Graduate Medical School and Hospital. Cloth. Price, \$1 net. Pp. 155, with 4 illustrations. New York: Paul B. Hoeber, 1914.

The author has undertaken to produce his lectures from the stenographer's notes without revision. The result is a certain familiarity of style that makes the topic interesting. The book deals in principles rather than in detailed facts, and is marked by strong common sense and conservatism. The principle is laid down that the strong man when acutely sick does not need food, although the nutritive needs of the aged and of poorly nourished persons should be kept in mind. In chronic diseases, on the other hand, the need of nutriment should be met by sufficient food even if other forms of treatment are interfered with and some symptoms are temporarily made worse. Therefore the author feeds the patient in chronic diarrhea even if some nourishment is lost by the increased number of bowel movements. Some tables and descriptions of special diets supply data for application to individual cases. The book tends to remove the arithmetical aspects of dietetics and place it on the high ground of rational therapeutics. We bespeak for it a cordial reception by the profession at large, for its subject appeals to every practitioner rather than to any specialist.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ALBERTA: Edmonton, September 15. Registrar, Dr. Cecil E. Race, University of Alberta, Edmonton.

IOWA: Des Moines, September 10-12. Sec., Dr. Guilford H. Sumner, Capitol Bldg., Des Moines.

MASSACHUSETTS: Boston, September 8-10. Sec., Dr. Walter P. Bowers, State House, Boston.

MISSOURI: Kansas City, September 28-30. Sec., Dr. J. A. B. Adcock, State House, Jefferson City.

NEW YORK: September 22-25. Chief of Examination Division, Mr. Harlan H. Horner, Department of Education, Albany.

West Virginia April Report

Dr. S. L. Jepson, secretary of the West Virginia State Board of Health, reports the oral and written examination held at Charleston, April 21-23, 1914. The number of subjects examined in was 10; total number of questions asked 100; percentage required to pass was 80. The total number of candidates examined was 16, including one osteopath, of whom 14 passed, including one osteopath, and 2 failed. Fifteen candidates were licensed through reciprocity. The following colleges were represented:

Supervisory Medical Officers in Germany

In Germany provision is made for a supervisory medical service in charge of district physicians known as *Kreisärzte*. Consul H. W. Harris at Frankfort, in *Daily Consular and Trade Reports*, June 9, 1914, describes the manner of appointment and duties of these medical officials. They are appointed by the state and are under the supervision of the state authorities in the various provinces. They may be called on to cooperate with local health authorities, mine and factory inspectors, federal insurance officers and others. Their duties embrace not only matters for the prevention of disease, but also duties which under American practice belong to coroners, medical examiners, boards of health, mine inspectors, undertakers, etc. In combating infectious diseases the local authorities must render assistance in carrying out the district physician's proposals. He is charged with the duty of maintaining intimate relations with private medical practitioners of his district for promoting knowledge about medical matters, medical societies, etc., and in making investigation in regard to outbreaks of infectious diseases he must consult with the private physicians who have cases under treatment. This applies to meningitis, lockjaw, child-bed fever, typhoid, diarrhea, relapsing fever, hydrophobia, glanders, trichinosis, meat- and fish-poisoning, snake-bite, etc., as well as to the usual infectious diseases. He must watch over general health conditions and see to the enforcement of the laws and regulations in regard to health, apothecaries, hospitals, other health institutions, midwives, etc. He is required to keep a record of all physicians, medical assistants, dentists, midwives, apothecaries and druggists with their clerks and apprentices, and must also keep a personal record of the status of every practitioner in his district, and must make it his particular task in conjunction with the medical practitioners of his district to warn in a proper way against the injurious doings of quacks, and must keep a watchful eye on persons who practice the healing art without permission and who assume titles in this connection to which they are not entitled. With the aid of the police he keeps a biographical record of quacks and illegal practitioners. He also inspects drug-stores, dispensaries and similar establishments, inspects the books and sees that illegal fees are not charged for prescriptions. He also keeps especial surveillance over midwives and their practice, and examines and passes on the fitness of persons who wish to practice midwifery. Besides these duties, specific instructions are given to district physicians in regard to housing, factory and hygienic conditions of the people, and on many other subjects. He is the medical authority to whom are to be referred all matters pertaining to the hygienic welfare of the people of his district. He may be employed full time on salary, in which instance he is not allowed to do private practice, or he may be on salary and fees, when he may be allowed to practice. In addition to the very modest salary, certain allowances are made for house-rent, office, care-taking, etc. Leave of absence for rest or on account of sickness is allowable each year, and after ten years of service as district physician, if incapacitated he is granted a pension for life.

Fly Larvae and Horse Manure

The Department of Agriculture has been conducting experiments to find a method of destroying flies by chemical treatment of horse manure (*Bull.* 118, Dept. Agric., July 14, 1914). Of the twenty-four chemicals tested, the best results were obtained from borax and calcined colemanite or crude calcium borate, which showed a larvicidal power of over 99 per cent. in nearly all trials. Borax not only kills the larvae but also prevents the eggs from hatching; calcined colemanite acts on the larvae alone. The minimum effective amount is 0.62 pound of borax and 0.75 pound of calcined colemanite with the addition of 2 or 3 gallons of water to 8 bushels (10

cubic feet) of manure, which will destroy practically all the fly maggots. In these small quantities the borax did not interfere with the normal fermentation of the manure. Since boron in large quantities inhibits the growth of plants, tests were also made to determine if the borax-treated manure exerted any such deleterious effect. Tests on tomatoes, peas, beets, radishes, kohlrabi, oats, corn, cucumbers, lettuce, apple seedlings and rosebushes were negative with the amounts of borax mentioned. Wheat appeared to suffer a temporary setback under heavy applications of borax. The department issues the warning that borax-treated manure has not been studied in connection with the growth of all crops, nor has its cumulative effect been studied. It recommends that not more than 15 tons per acre of borax-treated manure should be used, and that not over 0.62 pound of borax be employed for each 8 bushels of manure. The suggestion is made that borax be applied to floors and crevices in barns, stables, markets, etc., and to street sweepings, and water added as in the treatment of horse manure. Borax, which costs about 10 cents a pound at retail, may be had at 5 or 6 cents a pound in 100-pound lots; calcined colemanite sells for about 2 cents a pound in large shipments, and for about 4 cents a pound in smaller quantities. The department figures that the cost of borax treatment will be about 1 cent per horse per day, and that of treatment with calcined colemanite considerably less.

Training the Left Hand

Some time ago the development of left-handedness in children was warmly advocated by various persons not only because in this way reliance could be placed on both upper extremities for mechanical work, which would undoubtedly be of advantage in case of serious disturbance of the functions of the right arm, but also because the hope was entertained that by training the left arm, a second speech center might develop in the right hemisphere of the brain in the same way as the well-developed right arm corresponds with the speech center placed in the left half of the brain. The Berlin physician, M. Fränkel, was especially active in the advocacy of this plan; in fact, experiments in this direction were undertaken in various localities. The practical results which have been so far reported do not correspond in any degree to the optimistic expectations of the advocates of the method.

In 1911, Dr. Schäfer, on the basis of permission granted by the school deputation, collected statistics with reference to left-handedness among about 18,000 pupils of the Berlin public schools. These statistics show that 4.06 per cent. of all the children are left-handed, 5.15 per cent. of all the boys and 2.98 per cent. of the girls. The percentage of children in whom both hands are equally developed is very small, being only 0.21 per cent. The overwhelming majority, 95.73 per cent. of all children, are distinctly right-handed. In several school districts, among 448 teachers there were ten who were left-handed. L. Katscher's work on "Training the Left Hand" (*Die Ausbildung der linken Hand*) was the theoretical basis for the exercises to train the left hand. They included exercises in writing, arithmetic, manual training and gymnastics; especially in the last two systematic efforts were made. In general, the result showed that the possibility of employing the hitherto unused left hand at first excited great joy and marked interest, but the physical awkwardness generally was a great hindrance. This was particularly shown in writing, in which the mirror-writing and scrawling crows' tracks diminished the success of the instruction. In drawing, the success was relatively greater, especially when the drawings were made on the blackboard; also in manual training good results were obtained in building, plaiting and weaving. In gymnastics the special exercises such as bending the fingers, the hand and the left arm produced an increasing aptitude and skill.

The experiment was tried in 145 classes. Children to the number of 2,611 (1,497 boys and 1,114 girls) undertook these left-handed exercises. They were given up in three cases; in one class because the teacher was ill, in two others because these exercises were regarded as useless, time-consuming in

carrying out the instructions laid down by the school board, and a hindrance.

The outcome of the whole experiment shows that in no case could a preference for the left hand be developed. It may be trained to be a welcome assistant to the right hand, but never as a substitute for it. In teaching writing the complaint is made of a destruction of the esthetic sense and a deterioration of the hand writing. The children refused to write with the left hand, became nervous and worried over it, and increased intellectual development was in no case observed. Almost all those who gave an opinion were unanimous that the advantages stood in no relation to the expenditure of time, pains and patience.

Old Age Pensions in Denmark

For twenty years Denmark has had laws providing for old age pensions. Prof. Katherine Coman gives in the *Survey* the history of this legislation and its working, together with a statement of opinion as to the law, derived from an inquiry in that country concerning it. The pension is granted to persons over 60 years of age, either men or women, who are found to be worthy and in need. An unmarried woman is subject to the same conditions as a man. Wives, widows or divorced women are entitled to a pension equivalent to that which would have been awarded to the husbands. The amount of the pension is not fixed by law, but is left to be determined in each case. An attempt has been made in some communities to standardize the amount of the pension. This applies practically only to Copenhagen and Fredericksborg. A maximum pension was fixed, which differs for men and women, married couples and couples with children in the places mentioned above. A maximum is also fixed for other towns and the rural districts. The tendency has been for the amount granted to be increased from year to year, although the amounts are still very low, estimated on the basis of the cost of living in a country like the United States. These pensions seem to be becoming a heavy burden on the taxpayers of the communes and on the state treasury, which has assumed half of the expenditure.

In 1895 the average annual pension in Denmark cities, was 72.59 kroner (a krone is about 27 cents). In 1906 and 1907, the average had increased to 118.69 kroner. In 1892, the total number of beneficiaries under this pension law was 43,826. In 1911 it had increased to 79,289. The total expenditure had increased from 2,500,000 kroner in 1892 to 13,000,000 in 1912 and 1913. In an investigation of this form of provision for old age, it was found that the sums expended for poor relief outside the pension law have also increased. An inquiry by Professor Coman as to whether this amount was not regarded as a new form of poor relief, was answered by every one from taxpayer to administrator in the negative, though there were differences of opinion as to the desirability of such a law. Professor Coman states that there is no question that the economic injustice of leaving the workingmen in a condition in which they are liable to suffer from actual want or requiring them to accept poor relief has been satisfactorily terminated, and heavy burdens have been lifted from children, relatives and benevolent employers. The rapid increase on the demands on the public treasury, however, have startled even the best friends of the measure, and already modifications of the law have been suggested whereby workingmen are to be required to contribute, during their working years, to the fund for their later relief. Another plan suggested has been to standardize the pensions of the towns and rural districts, as in the case of the city of Copenhagen, in order that the amount of expenditure required be more certain than under the present arrangement. It has been proposed to reduce the number of beneficiaries by lowering the age limit to 65. It may not be easy to do this, since every laborer has a general practitioner, both of whom belong to the Social Democratic party. It is a well-arranged bibliography of the surplus which the employer consults the original literature.

Medicolegal

Malpractice in Treatment of Gunshot Wound

(*Dailey vs. Shaffer* (Mich.), 146 N. W. R. 192)

The Supreme Court of Michigan affirms a judgment against the defendant for malpractice while treating the plaintiff's husband for a gunshot wound in the calf of his right leg. The court says that the shot tore its way clear through the thick part of the calf, leaving a hole large enough to insert two fingers. The man was removed to his house, and the defendant arrived within a few minutes thereafter and took charge of the case. The wound was partially cleansed and some of the foreign matter removed, after which antiseptic gauze was inserted, and the leg was bandaged. Strychnin tablets were administered, as the patient was suffering from shock and loss of blood. After giving members of the family some instructions as to treatment during his absence, he left at about 11 a. m., after having been there an hour, and returned at 3 p. m., to find the patient somewhat improved. At this time, he remained about fifteen minutes. On the first visit, the defendant made some investigation to learn the extent of the injury, but did not go far enough with it to learn whether any of the arteries had been severed or punctured. On the second visit, he made no investigation in this respect. At 7 p. m. it was thought that the patient was bleeding too freely, and repeated attempts were made to reach the defendant over the phone, but without avail. At 4 a. m. next day, the condition became alarming, and a neighbor was dispatched for the defendant, but before he arrived the patient was dead. A post-mortem examination disclosed the facts that the posterior tibial artery was cut off and the popliteal artery was partially divided, and experts gave it as their opinion that the patient died from arterial hemorrhage. The negligence with which the defendant was charged was: First, a failure to ligate the severed and injured arteries; second, in failing to visit and attend to the patient as often and as much as he should have done. The defendant admitted that he did not inform himself as to whether the arteries were cut off or punctured, and it was shown by expert witnesses that he should have done so; that he should have found the bleeding point and stopped the hemorrhage. After he determined what course to pursue without this information, he was in no position, as a matter of law, to invoke the protection of the rule in emergency cases, but it was properly submitted to the jury to determine whether he did what was necessary to bring his treatment within the rule in emergency cases, that if a physician exercises his best judgment as to the treatment, he is not liable for negligence for an error of judgment in following one treatment rather than another. The other ground of complaint, as to whether the defendant gave the patient the attention and care which the case demanded, was likewise one for the jury.

Practice of Medicine by Chiropractor

(*People vs. Ellis* (N. Y.), 147 N. Y. Supp. 681)

The Supreme Court of New York, Appellate Division, Second Department, affirms a conviction of the defendant of the misdemeanor of practicing medicine within that state without any license or registration. The court says that the defendant claimed to be a chiropractor or doctor of chiropractic. He had a sign with regular office hours, and as a witness he admitted having treated about 200 persons for ailments of the stomach, chest, or spine, also for nervousness, hysteria, and diseases coming from pressure on the nerves. The prosecution proved by a witness whom the defendant had treated that the defendant first examined her ankle, pronounced the arch as having fallen, massaged the foot, and advised a different shoe. On a further visit he manipulated the patient's spine, which, speaking as a spinologist, he pronounced out of alignment in several places. He said he could restore it, but it probably would not stay the first time. He further gave the opinion that the nerves lead-

ing to the ankle might be so impinged on as to cut off the circulation. In view of the large increase of those who attempt remedies without drugs or instruments, legislatures in this and other states have found it necessary to deal with all who assume to treat or prescribe for physical ailments. The defendant's office-sign, circular and professional card, as well as his own frank admissions as a witness, all showed that he held himself out as able to diagnose, treat, and prescribe for pain, disease and injury. Rubbing and pressure on the human joints are old therapeutic agents. When accompanied by such attempts at diagnosis as the statement that a patient's pains in the ankle were caused by the spine, having come out of alignment through displaced vertebrae, the defendant's acts came within the statutory definition of the practice of medicine. He therefore was guilty of the misdemeanor of practicing medicine without a license, or being registered under the public-health law, Section 174. The information which charged practicing medicine without lawful authority between certain dates, and in particular on five days which it specified, was sufficient. The different acts going on to establish the unlawful practice need not be more particularly set forth in the information, as they simply made up one continuous offense.

Attending Physician Versus Experts on Mental Condition

(*Philpott et al. vs. Jones et al. (Ia.)*, 146 N. W. R. 859)

The Supreme Court of Iowa holds that in this case, in which the probating of a will was being contested on the ground that the maker lacked testamentary capacity, an instruction was properly refused which would have told the jury that "the attending physician is presumed to know the state of the mind of his patient, and these are facts that should be considered by the jury in determining the weight that should be given to their testimony." There is no presumption that a physician who is called to treat a sick man for his physical ailments, is better qualified to testify as to the mental condition of the patient, from the mere fact of attendance on his physical sickness, than is one who is trained to the treatment and who has large experience in the treatment of mental diseases. Besides, the weight to be given to the testimony of a witness depends on too many things to justify the court in limiting its probative force to one particular fact. The condition of the human mind at any stage of human existence is difficult of proof; perhaps the most difficult of any with which courts and juries are compelled to deal. Mental unsoundness, whether resulting from old age or physical sickness, is so various in its character and so different in its manifestations that it is often difficult for the most experienced experts, after most careful and thorough investigation, to trace it to any sufficient cause or to define its extent or its effect on the conduct of the individual. Even the most experienced alienists, with all the facts before them touching the conduct of the individual concerning whose mental condition the investigation is instituted, are often found widely differing in their conclusions as to the then condition of the mind under consideration. Mental unsoundness may exist which would render a man incompetent to make a will, notwithstanding to all outward appearances he seems to be sane to those with whom he comes in casual contact, who are not experts on the question.

Entitled to Recover Expenses and Compensation

(*Plumb vs. York County (Neb.)*, 146 N. W. R. 938)

The Supreme Court of Nebraska holds that a regularly licensed physician, who is paid a salary of \$5 per month for his professional services in treating the inmates of the county poor-farm and the county jail, may recover from the county the actual expenses incurred by him in quarantining, fumigating, and suppressing an epidemic of small-pox within his county, together with a reasonable compensation for his services. The court says that it appeared that the plaintiff was called on by the county to attend, quarantine, and fumigate in 132 cases of small-pox. His actual expense in connection with this service was \$260, and he charged the county \$726

for his professional services in that behalf. The county board disallowed his claim, and he prosecuted an appeal to the District Court. The cause was tried without a jury and the Court awarded him a judgment for \$790.35. The county sought to defeat his claim by contending that he was a member of the board of health, and therefore he could not have a return of the money expended by him in the suppression of the disease, and neither could he have compensation for his services rendered in that behalf. Moreover, it appeared that there was no contract entered into between the county and the plaintiff for the services in question, and there was a rule that required members of the board of health to serve without compensation. If the contention of the county was to prevail, however, then the public would be helpless to protect itself against contagious and epidemic diseases. It is easy to understand why the members of the board of health should receive no compensation for serving thereon, but it would be difficult to understand why a physician should be called on to serve the county in suppressing an epidemic and contagious disease without compensation. Many cases were cited to support the contention that an officer must perform all the duties of the office for the compensation provided by law, but those cases were not decisive of this controversy. The plaintiff was entitled to recover the expenses actually incurred and paid by him in the suppression of the small-pox epidemic in question, together with a reasonable compensation for his professional services. The judgment of the District Court was right, and it is therefore affirmed.

On Prohibiting the Use of Tobacco

(*City of Zion vs. Behrens (Ill.)*, 104 N. E. R. 836)

The Supreme Court of Illinois holds void, as an unreasonable interference with the private rights of the citizen, a city ordinance making it unlawful for any person to smoke tobacco in any form, or to have in his possession, any lighted pipe, cigar or cigarette, in or on any street, alley, avenue, boulevard, park, parkway, public passageway, depot, depot platform, depot grounds, hospice, hotel, store, post-office, or other public building or public place within the city. The court says that, recognizing that tobacco smoke is offensive to many persons, and in exceptional cases harmful to some, the court has no doubt that power exists to prohibit smoking in certain public places, such as street-cars, theaters and like places where large numbers of persons are crowded together in a small space. But this is quite a different matter from prohibiting smoking on the open streets and in the parks of a city, where the conditions would counteract any harmful results. The personal liberty of the citizen cannot be interfered with unless the restraint is reasonably necessary to promote the public welfare. In the broad language in which this ordinance was enacted it was apparently an attempt on the part of the municipality to regulate and control the habits and practices of the citizen without any reasonable basis for so doing.

Entitled to Show Who Employed Physician

(*Egner vs. Curtis, Towle & Paine Co. (Neb.)*, 146 N. W. R. 1032)

The Supreme Court of Nebraska says that it appeared that, after the plaintiff was injured, a physician, unknown to, and without authority from him, was called to treat his injuries, and, without any subsequent employment by him, continued to treat him for a considerable period of time. On the trial of the action which he brought against his employer to recover for his injuries, his counsel called the physician to the witness stand and attempted to show by him who employed him. That was not misconduct on the part of counsel. If, as a matter of fact, the physician was the physician of an insurance company that had contracted to indemnify the employer for injuries to its employees, and, by reason of that fact, was called to treat the plaintiff after his injury, the plaintiff had a right to show the fact as a circumstance tending to show that the defendant recognized a liability. If some insurance company was defending the case under the cover of the defendant's name, it was proper to uncover it.

Society Proceedings

COMING MEETINGS

6. Experimental Operations on Orifices of Heart.—Also published in *The Journal of Experimental Medicine*, July, 1914, and abstracted in *THE JOURNAL*, August 1, p. 428.

7. Bronchiectasis.—It is generally recognized, says Meyer, that a somewhat advanced, viz., a well developed, bronchiectasis is a surgical and not a medical disease. The operative treatment should be considered from the following points of view: *A.* Pneumotomy for draining the suppurating cavities. *B.* Operations done to compress the lung (collapse therapy). (1) By creating therapeutic pneumothorax—nitrogen insufflation; (2) pneumolysis with or without introduction of a tissue filling; (3) thoracoplasty, combines with, or without (4) phrenicotomy. *C.* Operations done to influence the pulmonary parenchyma, producing contracting plus carnification. (1) Transposition of the lung; (2) ligation of branches of the pulmonary artery, with or without subsequent thoracoplasty, pneumolysis and phrenicotomy—intrapericardial ligation of the first divisions of the pulmonary artery. *D.* Amputation of the diseased lung.

8. Surgical Aspects of Bronchiectasis.—The following points are emphasized by Mumford and Robinson. Granted that bronchiectasis is commonly the result of bronchial obstruction by foreign body, tumor or disease, the first indication in therapy should be the removal, if possible, of this

obstruction. Bronchoscopy for the removal of a foreign body has not infrequently arrested bronchiectasis. In the earlier stages of bronchiectasis, nitrogen gas injection producing artificial pneumothorax is indicated, and should always be tried.

Pleuropneumolysis, or extensive rib resection, is a dangerous procedure, with additional dangers in bronchiectasis. It should be employed only when adherent pleura prevents the introduction of nitrogen gas. Even then it is a dangerous procedure, and one of doubtful value. In late cases of bronchiectasis, when the disease is obviously confined to one lobe, lung resection is the sole hope of surgical cure. The attempt at lung resection at a one-stage operation has been attended with high mortality. Occasional successes do not prove that the one-stage amputation will become the method of choice. The authors hold that for the time being, at least, the general surgeon should first produce compression of the lung by artificial pneumothorax or pulmonary arterial ligation; second, and much later, he should excise. Meanwhile the student of thoracic surgery will develop the one-stage excision.

10. Conservative Treatment of Cystic Disease of Breast.—

Eighty-three cases in which cystic disease was present have been investigated by Greenough and Simmons and proved by pathologic examination of the tissue removed at operation, but all were cases in which only a partial removal of the diseased gland tissue was performed. The subsequent incidence of carcinoma in these cases, therefore, gives a further light on the tendency toward its development in cystic disease of the breast. In 14 both breasts were operated on—a total of 97 operations. In 59 cases partial plastic resection was performed, and in 32 a local excision was made of the affected portion of the breast. In 2 cases all of the gland tissue was subsequently removed by the plastic operation (subcutaneous amputation), and in 4 cases a later total amputation was done.

The subsequent histories of the 83 cases have been investigated. The length of time which elapsed from the first operation varies in these cases from one to seventeen years, an average of over seven years for each case. Four of the 83 patients, or 4.8 per cent., developed carcinoma of the breast—3 after partial plastic resection, and 1 after a simple excision of the tumor. Four patients have died of other causes, without evidence of any disease of the breast. Sixty-two patients are alive and well, and these with the four dead without recurrence, make 66 of the 83 cases, or 80 per cent., free from recurrence and apparently up to the present time, at least, cured of their disease by a partial operation.

Thirteen cases (15.6 per cent.) showed sooner or later a return of the disease. In 5 patients the disease returned in the other breast, and in 8 patients it recurred on the same side, in the gland tissue remaining after the first partial operation. One patient died ten years after operation with a broken hip. Another five years after operation with a cerebellar endothelioma. In neither case was there evidence of any malignant process in the breast, though both were reported to have had recurrence of cysts. Four patients refused operation, and were reported living and well but with cystic disease present—1 one year, and 3 five years after operation. The other 7 were operated on again, by amputation of both breasts in the greater number of cases, and reported well at intervals of ten, five, four, two, one and one-half years, seven months and one month later. Thus either recurrence of the cystic disease or carcinoma occurred in the breast first subjected to a partial operation in 12 cases out of the 83, or 14 per cent. In 16 cases, or 19 per cent., the patient failed to get permanent relief by the partial operation. In this connection it is of interest to note that in 19 of the 83 cases, or 23 per cent., the disease affected both breasts, although in a different degree. Of the 19, 14 had operative treatment on both breasts, and 5 had operation on one side alone.

The authors emphasize that the occurrence of carcinoma in cases of cystic disease, estimated at about 10 per cent. of all cases, demands radical treatment in all but the mildest cases. The operation of choice should remove all of the

gland tissue of the affected side, and, when the disease is bilateral, of both sides, this can best be accomplished by "subcutaneous amputation," leaving the nipple and areola, or by elliptical amputation. Where grave doubt as to diagnosis is present elliptical amputation is to be preferred. Local excision of nodules in the breast, suspected of being malignant, should never be performed. The operation of local excision or partial plastic resection should be restricted to the earliest and mildest types of cystic disease. In such cases plastic resection is the operation to be preferred.

12. Arteriovenous Anastomosis.—A view of Goodman's series of 16 cases shows six successes. Several of the cases which promised success, later required amputation (eight cases), but even these patients received temporary relief from pain. The results seem to warrant the conclusion that the procedure is well worth trying in suitable cases, as it affords the only hope, except amputation, for the patient threatened with gangrene. There were 13 end-to-end anastomoses, 1 side-to-side, and in 2 of the cases, an exposure of the vessels showed that an attempt to anastomose was not warranted, on account of the advanced stage of thrombosis of the vessels. In 2 of the cases with gangrene, a low amputation seemed to be satisfactory. Of the 8 cases which were failures, including 1 death, 1 was side-to-side anastomosis, and 3 of the remainder should not have been operated on on account of the presence of spreading gangrene.

13. Melanoblastomas of Foot.—The disease is one of advanced age. Males preponderate. In a few of the authors' cases there had been a lesion previous to the tumor, in 1 as long as eight years. These tumors spread by way of the lymphatics. The great viscera which are the usual site of blood-vessel metastasis are singularly free in this affection. The disposition to local recurrence is striking. The variability of the physical appearance is in striking contrast to the clinical similarity. In form they vary from small excoriated ulcers not unlike any indolent ulceration to large angry-looking, fungoid, pigmented masses. The variability in form is, however, not essential. They are all tumors which arise in the dermic or subdermic tissue and push through their covering, the difference in form depending on whether or not they just destroy the skin or project above it. The characteristic portion lies beneath the skin, not above it.

These tumors, the authors state, must be reckoned among the most fatal but in some of the early cases cure may be possible. Very early diagnosis is absolutely essential. Unfortunately when they reach the surgeon they have usually already been subjected to local irritation which has but stimulated their growth. Theoretically, at least, local treatment would cure them if done early. Yet there is never any assurance that the tumor is strictly localized. The tumor should therefore be excised in all cases. In early cases local excision should, theoretically suffice, but there is nothing in the literature to justify such a procedure. On the other hand, if dissemination has already taken place, amputation will avail nothing. The patient may as well in that event use his foot during the small span of life still remaining to him. The fungoid type should give a better prognosis than the ulcerous and should give more encouragement to radical operation. When glands along the iliac vessels are involved any operation is useless.

- 14 *Effects Observed in the Use of Mixed Toxins (Coley) in Sarcoma. T. W. Harmer, Boston.
15 Roentgen Diagnosis of Incomplete Forms of Pyloric Stenosis. F. H. Baetjer and J. Friedenwald, Baltimore.

14. Mixed Toxins in Sarcoma.—This paper is based on observations made since June, 1909, in the use of mixed toxins of streptococcus and bacillus prodigiosus (Coley) in 91 cases. Some were early cases in the series in which the doses were too small. Some cannot be traced, some were cases in which no pathologic report was obtained. Some were cases of microscopically proved carcinoma. Some were cases of proved sarcoma in which the toxins were adminis-

tered as a prophylactic against recurrence after operations which might of themselves have cured. There remain 32 cases; all of these were primary or recurrent, inoperable sarcomata, or cases in which the disease could not be eradicated at operation. All were proven by microscopic examination. All were under treatment at least three weeks. In all cases the results were free from vitiation by concurrent treatment. The average age of all cases is 33.8 years. The average duration of treatment was three months +. The average maximum dose was 11.9 minims. The maximum dose was 53 minims.

The cases are arranged in six groups, determined by the effect of the toxins. Group A includes those cases in which there was no appreciable effect (10 cases). Group B includes those cases in which the growths softened but did not diminish in size. There were 5 such cases. Group C includes those cases in which the growths disappeared, or practically disappeared, but returned. There were 5 such cases. Group D includes those cases in which growths disappeared but metastases simultaneously occurred. There were 5 such cases. Group E consists of one case in which the growth diminished in size but the tumor still persists. Group F consists of those cases which are apparent cures in which growths have disappeared and no metastases have occurred. There are six such cases. They have remained apparently well since conclusion of the treatment, respectively, one year, two months; two years; two years, seven months; two years, nine months; two years, eleven months, and two years, eleven months.

Harmer emphasizes that the treatment of primary or recurrent inoperable sarcoma with mixed toxins must be intensive. The increment of dose and the interval between injections requires some experience but, even after a considerable experience, this method of treatment is always uncertain and so distressing that, its institution is unjustifiable in any case in which operative measures of reasonable safety offer possible hope of removal. It should be instituted in no case unless proven microscopically to be sarcoma. Its institution is unjustifiable in all cases of inoperable sarcoma. The percentage of apparent cures may be regarded as varying from 9.4 to 18.8. Harmer's study suggests to him that the toxins offer no expectation of benefit in cases with multiple melanotic growths in cases with mixed cell growths, in cases with intra-abdominal growths and in cases arising from subcutaneous tissue or bone, excepting perhaps giant cell growths. It suggests that they may be legitimately tried in cases with single melanotic growths. It suggests that they are apparently of value in cases with sarcomata arising in nose and accessory sinuses, whether spindle cell, giant cell or round cell. The operative treatment of true giant-cell tumors gives, in the majority of cases, such good results that the toxins are not indicated. Their use is, however, warranted in those cases in which the growths are so situated that complete surgical eradication is impossible (such as giant cell tumor of the spine) and in these cases the attack should be primarily surgical, followed by toxin treatment.

25. Complement-Fixation in Gonococcus Infections.—About 60 per cent. of all cases of gonococcus infections investigated by Kolmer and Brown reacted positively to the gonococcus complement-fixation test. In the few cases of pyosalpingitis examined, 66 per cent. reacted positively. The highest percentage of positive reactions, 83 per cent., occurred in cases of arthritis, considered clinically as possible gonococcus infections. The authors regard the gonococcus complement-fixation test as of particular value in aiding the diagnosis of the nature of an obscure arthritis, in pelvic inflammatory diseases of women, to deciding whether or not a given case of urethral infection is cured or still harbors foci of living gonococci and aiding in the diagnosis and management of vaginitis in female children.

The reactions are not generally as satisfactory as those occurring in the syphilis reaction because the quantity of gonococcus antibody is much smaller unless grave and widespread gonococcus metastases exist, and the fixation of complement by bacterial amboceptor and antigen is not so marked as that occurring with syphilis reagin and a lipoidal extract. In a comparative study of a number of serums tested with both the antisheep and antihuman hemolytic systems slightly better results were secured with the latter. Gonococcus antigens to be of any value must be polyvalent. An antigen composed of a simple suspension of organisms in saline solution yielded 11 per cent. better reactions than filtrates. It appears that the bacterial protein, aside from the endotoxins, aids in the antigenic effect. Alcoholic extracts of gonococci possess little or no value. The occurrence of positive reactions in about 9 per cent. of cases of chronic gonococcus infections with antigens of staphylococci, streptococci and diphtheroid bacilli, indicates the active rôle these organisms may assume in these infections. The occurrence of about 5 per cent. positive reactions with an antigen of the micrococcus catarrhalis would indicate that this organism may be likewise active in chronic urethritis.

A study of antigonococcus and antimeningococcus sera with antigens of gonococci and meningococci, indicates the close biologic relationship of the gonococcus and meningococcus and while their respective amboceptors are most specific for their own antigens, in lower dilutions this specificity is not so apparent and the results constitute another example of "group" reaction similar to those occurring with the group of streptococci, diphtheria bacilli, spirochetes, etc.

26. Cultivation of Bacilli Partially Anaerobic.—Horton describes his method as follows: Employ an ordinary large test-tube such as is generally used in making potato cultures. In this insert a tightly fitting piece of thin glass which should be about three-fourths the length of the test-tube. Place plain agar-agar as culture medium in the tube and

insert a cotton plug. Sterilize the tube thus prepared. After this process slant the tube so that the agar lies high on one side of the central glass slide. Carefully observe the tube and note this, as exactness in this regard has a direct bearing on the success of the technic. The water of condensation will tend to collect at the bottom of the lower side thus minimizing the chance of surface spreading or contamination of the higher side. Streak the lower side with the *Bacillus subtilis*, taking care to cover the whole surface. Inoculate the higher side with some aborted material, amniotic fluid from an aborted calf, or the fluid from the interior of a cyst of the ovary. After inserting the cotton plug, push it down into the tube and place a tightly fitting rubber cork over it to make the tube air-tight. The tube thus prepared must be incubated at 37 C.

Within two to three days growth will take place on the higher side in which the suspected material was planted, thus enabling a further study of the organisms or colonies present. Horton has had excellent results in using this method for the cultivation of the *Bacillus bifidus*, Tissier, and the *Bacillus abortus*, Bang. To aid in this practice it is suggested that test-tubes with the glass slide be made all in one piece, thus precluding all possibility of the *Bacillus subtilis* contaminating the desired growths. So constructed, the tubes may be slanted in the usual way, there being no need for having one side of the slant higher than the other.

28. Classification of Streptococci by Fermentation.—Analysis of their experiments seems to justify Hopkins and Lang in drawing the following conclusions: The streptococci usually concerned in severe infections in man may be differentiated from the common saprophytic types by fermentation tests. The tests are best performed in infusion broth colored with litmus, containing 2 per cent. or more peptone and 1 per cent. of the fermentable substance. The initial reaction should be between 0.0 and 0.5 per cent. normal acidity (phenolphthalein). Only a complete change of the litmus to pink should be considered positive. The useful test substances are lactose, salicin, raffinose, mannite and inulin.

On the basis of these reactions Hopkins and Lang can recognize the pathogenic and six saprophytic groups: (a) Pyogenic group; characterized by fermentation of lactose and salicin. (b) Four salivary groups; two characterized by fermentation of raffinose, one by fermentation of inulin, and one by failure to ferment salicin, raffinose, mannite or inulin. (c) Fecal group; characterized by fermentation of mannite. (d) Equine group; characterized by failure to ferment lactose. The streptococci in this class are saprophytes and are commonly found in horse dung. Titrations of the amount of acid formed in fermentation are of no value in classification. Tests for ability to hemolyze human blood are of value in that highly pathogenic strains are usually strongly hemolytic. The type of chain formation, the milk coagulation test, and the neutral red reaction, are not reliable as bases for classification.

29. Anaerobic Cultures in Scarlet Fever.—In blood-cultures from 24 cases made anaerobically by Dick and Henry positive results were obtained in 20 cases. A comparison of the kind of organisms found in these blood-cultures with the organisms present in the throat and urine would indicate that during the acute stage of scarlatinal angina, organisms enter the blood-stream in considerable number and are excreted in part at least in a viable condition through the kidneys. The authors suggest that the excretion of living bacteria through the kidney may have some connection with the development of scarlatinal nephritis. A number of organisms are described which are commonly associated with scarlet fever, some of which produce rash in guinea-pigs, but the authors were unable to say that any of these animals really had scarlet fever.

Hemolytic streptococci were found in the blood in 7 cases, in the lymph-nodes in 2 cases, in the spleen in 2 cases and in the urine in 3 cases. Very small streptococci were isolated from the blood in 5 cases. They were much smaller than the hemolytic streptococci and did not as a rule affect

blood. Gram-negative diplococci were recovered from the blood in 1 case, from the urine in 2 cases, and from the throat in 1 case. Large gram-positive diplococci were found in the blood in 3 cases, in the urine in 2 cases and in the throat in 1 case. Diphtheroid bacilli were recovered from the blood in 1 case, from the urine in 1 case and from the throat in 2 cases.

31. Toxins of Intestinal Obstruction.—Gurd's experiments prove that vascular disturbances, namely, venous stasis, are equally as potent as occlusion of the lumen in the development of a poisonous substance in the intestinal mucosa, and that the substance produced in this manner is likewise a splanchnic paralyzer. The development of the poisonous material depended exclusively on vascular disturbance of the gut wall in a number of animals which were operated on and the portal veins or its branches ligated. In all of these operated animals the same type of fluid, which possessed the same toxic properties as the fluids found in closed duodenal loops, was discovered.

Dogs in which the portal vein, or the branches thereof draining the upper half of the intestinal tract, was ligated, died regularly within fifteen to eighteen hours. The animals never completely recovered from the stupor of anesthesia and were frequently found dead in exactly the same position in the cage as when returned from the operating room. The intestines, pancreas, and kidneys were found deeply cyanosed and the heart blood unduly fluid. The lumen of the intestine contained fluid blood-stained material, as a rule of a more watery consistency and deeper purple color than that found in cases of gut occlusion. The intestinal contents were collected from such animals and the cyanosed mucosa scraped off and placed in saline solution under toluol for extraction. Since the mucosa itself appears to contain a greater content of the toxic principle than does the content of the lumen, it would appear that the substance responsible for the intoxicating symptoms is the result of tissue autolysis rather than a bacterial product.

Gurd says it remains to be proven whether the death of the individual in cases of portal obstruction is due to the absence of the liver activity or to the development and absorption of the intestinal toxin, or of a combination of these two factors, and his experiments indicate that the effect on the nutrition of the intestine may be a sufficient cause for the untoward manifestations.

33. Bovine Mastitis and Human Streptococci.—The authors claim that hemolytic streptococci of human origin may cause mastitis, lasting for several weeks in cows. This time roughly corresponds to the duration of milk-borne epidemics. The streptococci may gain entrance through an abraded or injured surface of the teat. It appears possible, therefore, for mastitis in cows to be produced by an infection from the milker whose hands are contaminated perhaps from a sore throat. Mastitis results promptly when the cocci are injected directly into the udder by means of a catheter. The mastitis may exist without physical evidence. A caked bag may not occur, though pus and streptococci in large numbers are being secreted in the milk. Stringy, ropy, or gargety milk may or may not occur during the course of the mastitis.

In order to detect such infections, it might be necessary to examine milk from each quarter for bacteria and for pus. This may explain the failure to detect the source of the streptococci in some of the epidemics of sore throat. No change was noted by Davis and Capps in the cultural or pathogenic properties of the streptococci after growing in the udder of a cow for four weeks. The presence of various contaminating bacteria tend to inhibit the growth of hemolytic streptococci in milk.

35. Purpura with Bacillus Mucosus in Blood.—Clinically, the case studied by Weil and McMeans was a progressively severe bacteremia in which cultures of the *bacillus lactis aerogenes* were obtained during life from the blood, urine and prostatic secretion. Purpura, although a late manifestation, was the result of this infection. On account of the systemic reactions after each surgical interference (passing sounds), of the urethra, the authors feel convinced that this

was the point of entrance of the infection into the bloodstream. The authors suggest that probably infection of the genito-urinary tract by bacteria of the mucosus group is more common than is realized.

38. Quinin Treatment of Rabies.—The quinin treatment was tested by Cumming against fixed virus, as well as, against street virus. The former was a six-day virus, while the latter killed rabbits in about ten days, and guinea-pigs in eight days. The virus was given intracranially; the bisulphate of quinin was used in all experiments, the injections being intraperitoneal. The results were negative. The experiments were controlled both as to the infectivity of the virus and as to the absence, for the most part, of untoward symptoms from the quinin treatment. The dose of virus in most of the tests was not much larger than the smallest infecting dose. This amount of the virus is approximately 1/200,000 part of the total virus in the brain and spinal cord of a rabbit at the beginning of the paralytic stage. Inasmuch as the quinin failed as a preventive measure against extremely small doses of virus in actual tests, Cumming asks whether it cannot reasonably be assumed that this method of treatment is of no curative value in cases of hydrophobia manifesting symptoms in which the amount of virus would be many thousand times greater? In the absence of protection by quinin against small doses of virus, even when a series of daily injections of quinin is given preliminary to the injection of rabic virus, Cumming says, we cannot expect favorable results from quinin after symptoms of hydrophobia have developed.

40. Vaccines in Experimental Streptococcal Arthritis.—Concentrated antistreptococcus serum was prepared by Moore according to the methods employed in preparing concentrated diphtheria antitoxin. Fifty-two strains of streptococci were used including viridans and hemolyticus, as well as strains from cases of epidemic sore throat. The strains were isolated from patients having tonsillitis, alone or complicated with acute or chronic arthritis, endocarditis, serositis, nephritis and pyorrhea. The virulence of many strains was tested on rabbits; thirty-four produced acute or chronic arthritis in these animals. Four series of rabbits were injected with this serum: (a) after the establishment of acute arthritis; (b) immediately after receiving live streptococci; (c) before the injection of the live streptococci; and (d) before and again after receiving the living streptococci. In none of these groups did the concentrated serum appear to have any preventive or curative effect on the acute arthritis. Experimental streptococcal arthritis was either prevented by, or ran a much milder course after, prophylactic injections of a homologous streptococcus vaccine. An immunity was produced which persisted over forty days in at least one case. The immunity appeared to be intimately associated with, and probably dependent on, the production of opsonins. Endocarditis and nephritis were less frequent in the vaccine-treated rabbits than in the controls.

45 *Problem of Infection in Tuberculous Families. J. B. Hawes, 2d, Boston.

46 Before and After-Care of Tuberculous. E. Hochhauser, New York.

44. Fresh Air and Proper Food in Treatment of Tuberculosis.—All substances Bellis considers proper food for the tuberculous patient that supplies in an easily digestible form and in sufficient quantities all of the elements that go to make up a normal, healthy human being. To promote the eating and digestion of the various materials represented by the classification constitutes the problem of the physician or institution, that would assist nature to the utmost in combating tuberculosis. Primitive man lived in the great out-of-doors and appeased his hunger with such substances as were most easily obtained. Cookery was an unknown art and it may be more than a mere incident that infectious

diseases have multiplied in direct ratio to the extent with which the human race have demanded that the life of food be destroyed by fire before being eaten.

In this age of so-called civilization, people, sick or well, insist that what they eat must appeal to their senses of taste and sight, rather than to a clear complete knowledge of what constitutes nutritious and digestible food. It is somewhat doubtful, says Bellis, if we could return suddenly and completely to the food of primitive man without dire consequences. In the present day we are forced to compromise in the matter of food. The individual patient's taste, digestion, and power of elimination must be considered, together with the economics of the problem. The great majority of persons ill with tuberculosis, and other diseases as well, are finicky in their choice of food. Misdirected sympathy and "mollycoddling" by parents, neighbors, friends, and too often physicians, are responsible for this state of affairs.

The food to be consumed must be rich in those principles most essential to metabolism. Milk stands at the head of the list, for it contains in goodly proportions all of the required elements. Occasionally the taste of milk is repulsive. Where this objection is present, the flavor of the milk can be easily changed by the addition of any one of the numerous spices and extracts. The products of milk, butter and cheese are also exceedingly nutritious. Bellis places eggs second on the list. In their raw state they are especially rich in albumen and fat, easily digested, and ordinarily readily obtained. Beef occupies third place. Raw beef Bellis believes to be a most valuable substitute for raw eggs. Pork in the form of breakfast bacon and ham, the former for its fat content, and both for the intestinal antiseptics which are introduced in their curing, must not be forgotten. Next in importance is a generous mixed diet of vegetables. Not alone because of the very nutritious properties of many of them, especially the cereals and legumens, but also on account of the desirable addition of fats in the form of cream, oils, butter and suet used in their preparation. Coarse vegetables act as a "scrubbing brush" to the entire alimentary canal, cleansing it and stimulating the flow of the digestive juices. The fruits come under this heading and when eaten at appropriate times furnish to the body many elements of great value. Because of their laxative properties, fruits will obviate the necessity for pills in the dietary of many individuals.

45. Family Tuberculosis Infection.—Tuberculosis infection takes place chiefly in childhood years in the intimate contact of family life. There are three classes of tuberculous, says Hawes, which are the chief sources of family infection, the unknown case, the known case treated in his own home, and the returned sanatorium or hospital patient. The last class of returned sanatorium patients is the most important one and best repays our efforts. The responsibility of the State toward its patients, Hawes states, does not end when the patient is discharged nor does the responsibility of the municipality end when the patient leaves for a State sanatorium. Cooperation between State and local forces must be constantly striven for. Tuberculosis is primarily a local problem but the State may well direct and advise but not replace local work.

Hawes' paper is based on a study of 600 patients, discharged from various State sanatoriums. The great majority of them, approximately 83 per cent. were in the advanced or moderately advanced stages of the disease at entrance to the sanatoriums, while nearly 50 per cent. were discharged with positive sputum and with the disease still active. These 600 patients, including in these figures only the immediate members of the family, exposed 2,601 others to this disease. Of these 2,601 individuals, only 597 or 23 per cent. had ever been examined for tuberculosis, despite the fact that at the patient's admission to the sanatorium his physician as well as the local board of health were at once notified so that the other members of the family might be examined. Of these 597 exposed patients, who were examined, 75 or 12½ per cent. were found to be positive cases of tuberculosis.

There were 966 children, 15 years and under among those exposed individuals. Of these 362 or 38 per cent. had been examined and 38 or 10½ per cent. found to be positive cases.

The aims in Massachusetts are to have a trained social worker in each institution. It will be the duty of such a person to become acquainted with the patients, devoting her attention especially to those about to leave, finding out their plans for the future and preparing the way for them. In addition to this there should be one or more field workers for each institution. The work on behalf of the State will be to direct and encourage such local work.

81. Abstracted in THE JOURNAL, Dec. 20, p. 2270.

84. Surgical Treatment of Acute Abdominal Diseases.—Du Bose summarizes his paper as follows: 1. There is a preventable death-rate of approximately 7 per cent. in acute abdominal diseases. 2. To overcome this a diagnosis of at least the presence of an acute abdominal condition must be made at the first visit or less than twelve hours after its onset. 3. To appreciate that early operation is the safest of all treatment. That the measures advised by the advocates of masterly inactivity are never safe, are a last resort, to be used only on those unreasoning people who refuse surgery, or on those who are seen late in the disease, and on these only until they can be brought to a hospital and have had operative relief. 4. To stop teaching and reporting statistics of cases treated by the expectant plans without paralleling such records with those in which immediate diagnosis and prompt surgical operations are done and a comparison of results in each series. 5. To encourage a more intimate relation with the internist and have him witness operations and there study the living pathology. 6. To let surgeons and internists appreciate the fact that the symptoms are not always in direct ratio to the severity of the unseen pathologic process.

1. Intramuscular Injections of Antitoxin.—Intramuscular have entirely supplanted subcutaneous injections of diphtheria antitoxin at the Grove Hospital. Without preliminary washing the outer side of the thigh in its middle third is painted with 2 per cent. solution of iodine, the needle is driven deep into the body of the vastus externus, and the injection is given in the ordinary way. Twenty thousand units (= 50 c.c.) can readily be injected even in small children, but the authors have never exceeded this dose at one time. Their youngest patient, aged 2 weeks, received 4,000 units for nasal diphtheria without any ill-effects. Directly the needle has been withdrawn after injection, the site of puncture is again painted with the iodine solution and a collodion scab is applied.

The thigh is preferred to the gluteal region not only because there is less probability of injuring important vessels or nerves but also because the thigh muscles are much more compact and exercise greater pressure on the injected fluid, rendering absorption more rapid. Not only is the actual injection much less painful, but the subsequent pain which often causes a restless night and persists for two or three days after subcutaneous injection, is ill-marked and often entirely absent. It is superior to the intravenous method.

not only in the greater simplicity of its technic, but also in the less rapid excretion of antitoxin after injection. The more rapid absorption of antitoxin by the intramuscular route is shown, not by the effect on the faucial or laryngeal process, but by the lesser incidence of paralysis, especially of a severe kind.

- 5 *Medicine from the Chemical Standpoint. A. E. Garrod.
- 6 *Surgeon of the Future. J. Bland-Sutton.

5. Medicine from the Chemical Standpoint.—After touching on the foundations of medicine, the progress of chemical science and biochemistry, Garrod discusses generally, the investigations made into the proteins and other compounds, the specificity of chemical structure, the metabolic activities of the living organism, the regulation of metabolism, inborn errors of metabolism, protective mechanisms against toxic agents, metabolic disturbances due to disease of organs, deficiency diseases, influence of chemical knowledge on the practice of medicine, chemistry in diagnosis, dietetics, therapeutics, empiric and scientific. Concluding, he says, that the reason the progress of medicine has been more rapid in recent years than ever before is due to the cumulative advance of science as a whole. Modern physics and chemistry, and the borderland science of physical chemistry, have rendered possible modern physiology and pathology, and on the foundation thus provided is being raised the stately edifice of a modern medicine, in which the scientific spirit shall have freer play than heretofore.

6. Surgeon of the Future.—Speaking of the surgeon of the future, Bland-Sutton says that surgeons are of two types: they are either craftsmen or biologists. The surgical craftsman invents variations in technic—metal plates, wires and screws for bones; or fancy methods of suturing wounds. Some expend their ingenuity on surgical cutlery and improve the knives and needles. The utility of a simple tool such as the clip forceps is inestimable. In spite of much ingenuity among surgeons an ideal ligature material awaits discovery. Clever contrivances like the laryngoscope, bronchoscope and cystoscope have revolutionized special branches of surgery. Another useful instrument, the esophagoscope, requires for its successful use a surgeon with the instincts of the sword swallower and the eye of a hawk.

The biologic surgeon studies pathology in its broadest aspect and investigates, in the laboratory, problems of morbid anatomy and bacteriology. The diagnostic value of reports issued from the laboratory by the pathologist and the bacteriologist, to be of value, must be estimated with the help of clinical experience. If the surgeon has had no experience in bacteriologic methods he must accept the reports from the laboratory with the hopefulness of a patient swallowing physic compounded from a prescription he does not understand and which he is often unable to read. The training of surgeons in clinical pathology is of great importance, and it requires little foresight to recognize that for men ambitious to attain high places in surgery the high road lies through the pathological institute.

- 9 Etiologic Controversy anent Beriberi with Some Remarks as to Milled Rice. H. D. King.

8. Clinical Report of Rotunda Hospital.—The Hospital Staff of the Rotunda Hospital attended 4,136 labors from November, 1912, to November, 1913, with a mortality of 0.41. Seven deaths occurred in the extern department, eleven deaths in the intern department. Four deaths were the result of septic infection, one the result of accidental hemorrhage, one the result of unavoidable hemorrhage, and one the result of pulmonary embolus. There were twelve cases of unavoid-

able hemorrhage. Three mothers died—one of pyemia with thrombosis of the right ovarian vein. In the second case—one of central placenta praevia—bipolar version was performed, but the patient collapsed immediately after. The postmortem examination showed fatty degeneration of the heart. There was no hemorrhage after the version was completed. The third death also occurred in a case of central placenta praevia at term. There had been intermittent hemorrhage for four weeks before admission. Bipolar version was performed, and the patient delivered herself spontaneously four hours later. The postmortem examination showed that there was a tear of the cervix involving the bladder.

There were 24 cases of contracted pelvis. In four cases delivery was spontaneous. In 5 cases the forceps were applied, and delivery effected. In 2 cases, internal podalic version was performed. In 1 case, the child was extracted as a breech presentation. In 7 cases, cesarean section was performed, and in three cases pubiotomy was performed. Two patients died after cesarean section, both from septic poisoning. In one case of pubiotomy, the piece of bone between the saw-cut and the symphysis came away during the puerperium. This occurrence made not the smallest difference to the patient's power of walking. If anything, she walked better, and at an earlier date, than do the average number of pubiotomy patients. This patient subsequently delivered herself spontaneously in the hospital. There were 13 cases of prolapse and presentation of the cord. Five children were born alive, and 8 were born dead. There were only 5 cases of eclampsia. All the mothers recovered, and 4 children out of 6 were born alive. The forceps was applied in 64 cases. All the mothers recovered, and 54 children were born alive.

10. Gastric Ulcer Treated by Gastrostomy. — Cheyne believes that the question of gastrostomy is worth while considering in cases of adherent ulcers nearer the pyloric end which cannot be excised, in preference to gastro-enterostomy and closure of the pylorus. The advantages are very great. In the case of stricture of the urethra the quickest way of getting rid of the induration of the walls is to tie in a catheter for a few days and it seems to Cheyne, that the same result would probably follow in an indurated ulcer of the stomach. He would, of course, combine infolding of the ulcer with the gastrostomy whenever possible. While gastrostomy has not previously been suggested as a method of treating gastric ulcer, jejunostomy has been carried out in a considerable number of cases of ulcer of the duodenum on much the same principles, but although it has its warm advocates the idea does not seem to have taken hold. It seems to Cheyne that jejunostomy for duodenal ulcer does not possess the advantages that gastrostomy offers in the case of certain gastric ulcers. Ulcer in the duodenum seems to set up, and keep up, hyperchlorhydria and movements of the stomach and this may continue even though the patient is fed through a jejunostomy opening. Cheyne suggests that even in cases of duodenal ulcer, a gastrostomy with passage of the tube well down the duodenum, combined with infolding of the ulcer, might act better than jejunostomy, and might

possibly take the place of gastro-enterostomy and occlusion of the pylorus in cases in which the infolding of the ulcer did not produce serious constriction of the lumen of the duodenum.

In a case cited there was an ulcer of considerable size on the posterior surface of the stomach, high up near the cardiac end and firmly adherent to the parts behind, and on the anterior wall of the stomach at the same point there was also a commencing contact ulcer. The conditions were most unfavorable for excision. What Cheyne did, therefore, was to leave the ulcer alone and to perform gastrostomy beyond the ulcer by Witzel's method, pushing the catheter through the pylorus and for about 3 inches along the duodenum. The patient was fed through the tube very soon after the operation, and the tube was left *in situ* for six weeks, when it was removed and the wound allowed to heal up. No food was given by the mouth for five weeks. The immediate result of the operation was that the patient at once lost all pain and discomfort from which she had previously suffered, and rapidly began to put on flesh and regain strength, and there was no trouble about the wound which healed in a few days, except, where the tube passed down to the stomach. When tested with food by the mouth at the end of five weeks no discomfort was caused, and on leaving out the tube a week later the wound closed in a few days and since then she has had no further trouble.

12. Internal Derangements of the Knee.—Speaking of luxation of the internal semilunar cartilage, Jones says that he refuses to operate in any case which he sees immediately after the first displacement, as so large a proportion of such cases get well under appropriate treatment, nor does he encourage operation in cases in which the recurrent trouble is painless and is never followed by effusion into the joint. He strongly advocates operation in cases in which the recurrence is sometimes followed by acute symptoms and encourages it in all recurrent cases in which a strenuous athletic life is a means of livelihood or a physical necessity. Operation is a positive necessity in the case of men who work among moving machinery or stand in positions in which a yielding knee may mean disaster. He has operated on patients from 12 to 60 years; age, therefore, is not a contraindication. An argument in favor of operation is the occurrence of tubercle and so-called rheumatoid trouble as a direct result of the irritation of a displaced cartilage. Further, a knee which has been the seat of trauma is very susceptible to infection, and he is, therefore, careful not to operate during the presence of effusion nor to move it during operation for fear of the ingress of air or dust.

18. Suture of the Levator Ani Muscle.—The essential features of the operation devised by Jellett are: (1) The careful dissection of the necessary amount of vaginal mucous membrane off the rectum; (2) the exposure and suture of the separated levator ani muscles; and (3) the careful approximation of the cut edges of the vaginal mucous membrane in such a manner as to leave no projection or redundancy. The operation is carried out as follows: The extent of the perineal tear is carefully determined, and its anterior edges are marked out by bullet forceps. A third bullet forceps is applied to the perineal skin just behind the posterior edge of the tear. The position of the separated edges of the levator ani is determined by palpation through the mucous membrane of the vagina. An incision is then made from side to side along the line of junction of the skin and the vaginal mucous membrane. This incision cuts through the skin and any underlying scar tissue. A flap of vaginal wall is then dissected up off the underlying rectum. At its lowest part it is firmly held to the rectum and the sphincter ani by cicatricial bands, the result of the old cicatricial healing. As soon, however, as these have been cut through the separation of the remainder of the flap by blunt dissection is an easy matter.

When the dissection of the flap is complete a triangular space is exposed, which is bounded laterally below by the remains of the superficial vaginal and perineal muscles, and at a deeper level by the pubo-coccygeal fibers of the levator

ani muscle, while its floor is formed by the rectum. It is then an easy matter to catch the edges of the levator with clip forceps or dissecting forceps, and to draw them downward and inward until they meet in the middle line. If the separation and atrophy of the muscle are marked, then it may not be possible to draw the edges down sufficiently, but in the great majority of cases they can be brought into view. Three or four interrupted sutures of catgut are then passed through them from side to side, so that when tied they will approximate them in the middle line; for the present, however, they are left untied.

The next step is to trim the vaginal flap into proper shape, so that when the operation is complete there may be no redundancy. The cut edges of the flap are then brought together by a continuous catgut suture passed from above downward, and ending at the vulvar orifice. This being done, the catgut sutures in the levator muscle may be tied. The last step consists in the introduction of silkworm gut sutures passed so as to close the skin edges of the perineal wound. These sutures are passed from side to side, and traverse the skin and the remains of the superficial perineal muscles and also the elevator muscle, so as to supplement the buried catgut sutures. Any bleeding vessel, if of large size, should be caught and tied, but, as a rule, the best method of stopping bleeding is by proceeding rapidly with the operation.

19. Treatment of Cancer of the Uterus.—From 1896 until Dec. 31, 1913, Wilson operated on 596 cases of uterine cancer. Of these, in 67 the disease affected the uterine body. Among the 67, 15 vaginal hysterectomies with no mortality, and 29 abdominal hysterectomies with 3 deaths, were performed. Until the end of 1913 there were 529 cases of cancer of the cervix uteri. These can be conveniently divided into two groups according as operation by the vaginal or the abdominal route was the method of choice. In the first period, lasting until the end of 1905, there were 246 cases of which 37 were operated on by the vaginal method with one death, and 7 by the abdominal route with 6 deaths. In the second period, from Jan. 1, 1906, to Dec. 31, 1913, 283 cases were seen, among whom 20 were operated on by the vaginal route with no deaths and 72 by the abdominal with 8 deaths. The total immediate mortality of the vaginal method has been 57 cases with one death, or less than 2 per cent.; and of the abdominal, 79 operations with 14 deaths or 17.7 per cent. The great majority of abdominal hysterectomies were performed by Wertheim's method. The ratio of operability has steadily increased; in the years 1896 to 1899 it was 14 per cent.; in the last four years it has been more than 36 per cent.

The total five year results up to June 30, 1909, have been investigated and show that, with an increased operable ratio and the adoption of the abdominal method of operation the absolute curability of Wilson's cases have risen from 5.5 to 10.2 per cent. Of the patients surviving operation 16 of 51=31 per cent. of the vaginal, and 10 of 23=43 per cent. of the abdominal, remained well and free from recurrence for five years and upward.

- 28 Roentgenoscopy of the Stomach and Intestines. (Examen du tube digestif aux rayons X.) Bienfait.

20. Acquired Myotonia.—The young man's general health in the case reported by Beco has not been impaired by the intermittent severe contracture of the various groups of

muscles whenever he attempts to use them. He is robust and apparently free from inherited or acquired taint and had always been healthy until two abscesses developed on the right foot a year ago. The contractures occur even during sleep, but the sensibility and responses to electric tests are approximately normal. This justifies a more favorable prognosis than with ordinary myotonia, Beco adds.

22. Gunshot Wounds of the Abdomen.—Delrez and Lenger do not agree in their views on this subject. The latter advocates abstention as long as there are no signs of internal hemorrhage or other disturbance, while Delrez pleads for a prompt laparotomy with every bullet wound of the abdomen so as to ascertain and remedy any injury of the viscera. Each presents an array of cases which apparently sustain in turn each of the divergent views.

26. Dislocation of the Metatarsus.—Lenger remarks that divergent dislocation may almost be said to be merely the exaggeration of a physiologic movement. Reduction under a general anesthetic should be done at once if the dislocation is seen before the foot is swollen. When edema has developed, roentgenoscopy from the front and side may be necessary to ascertain the true condition. The main point in treatment is to restore the first metatarsal bone to place. When this is accomplished one can be content without attempting more. It might be imprudent to cut into the foot to restore the four other metatarsal bones to place. But if the first metatarsal bone cannot be reduced without operating, do not hesitate to expose it; it is possible that reduction of an intervening tendon may be all that is necessary. When the foot is crushed and amputation becomes necessary, if the first metatarsal bone can be saved, the functional use of the foot is retained and the gait not affected. This is because the foot is really made up of two parts, both triangular, a rear and internal tarso-metatarsal part, constituted by the seven bones of the tarsus and the first metatarsal bone. This is the strong arch of the foot, the arch of strength and movement; the arch rests on two supports: on the heel at the back and on the head of the first metatarsal bone in front. These two abutments support the weight of the body in walking and standing. The other part of the foot comprises the last four metatarsal bones, and it serves only to maintain the balance of the foot. Two tendons passing across the hollow of the foot define and separate the two parts. Lenger insists that the surgeon should feel that his task is done when he has succeeded in reproducing the arch of strength and movements. The rest of the foot can be left unmolested. Reexamination of one patient ten years after amputation of the last four metatarsal bones, run over by a wagon, shows perfect control of the foot. It is held and used normally, thanks to the preservation of the entire tarsus and the first metatarsal bone.

27. Megacolon.—Dubois' patient is a boy of nearly 12 with pronounced Hirschsprung's disease; extreme constipation had been the rule since early infancy, the stools were fluid, the peristalsis of the colon abnormally intense; the abdomen measured 71 cm. Of late there had been intermittent, more or less complete obstruction of the intestinal tract. Although the stools were fluid they were not abnormally frequent except when diarrhea alternated with inveterate constipation. Colitis is the rule, and there may be ulceration. The food should be such as to leave little waste, and the bowel should be rinsed out through a long soft tube with tepid water containing a teaspoonful of sodium bicarbonate and one of salt to the liter. This softens up impacted feces and promotes its expulsion; in his case the girth went down from 71 to 55 cm. in five days under this treatment. Dubois does not approve of operating on children under 5 except in emergencies. In the cases on record operative treatment on 14 infants was followed by 100 per cent. mortality; in 28 between 2 and 5, the mortality was 40 per cent.; in 46 between 5 and 15, it was 26 per cent.; in 41 between 15 and 50, it was 27 per cent. and in 14 patients over 50, it was 85 per cent. Colostomy should be merely the first step of the more complex operation. Taking up a fold in the colon,

fixation or colostomy are incomplete and do not do much good, and resection at one sitting is dangerous. Unilateral exclusion and implanting the ileum in the sigmoid loop is much better in most cases.*

Bulletin de l'Académie de Médecine, Paris

LXXVIII, Nos. 26-28, pp. 879-994 and 1-61. Concluded from p. 611

- 29 Gratifying Results of Special Training for Certain Mentally Defective Children. (Adaptation sociale des enfants psychonormaux éducatibles.) J. Roubinovitch.
- 30 *Improvement of Myxedematous Boy of 14 after Graft of Monkey's Thyroid. (Greffe de la glande thyroïde d'un singe à un enfant atteint de myxédème.) Voronoff.
- 31 *Ascaris in Pyopneumothorax; Eighth Case on Record. R. Blanchard and M. Letoux.
- 32 Morphine Acted on by Yeast as Analgesic. (Analgésie obstétricale.) Ribemont-Dessaignes, Bazy and Bourquelot.
- 33 Liver Lesions with Amebias Seven and Eighteen Years after Latent Infection; Two Cases. (Amibiase hépatique tardive de forme nodulaire.) C. Achard and C. Foix.

30. Graft of Monkey's Thyroid Improves Myxedema.—Voronoff's patient was a boy of 14 who had developed myxedema after measles at the age of 8. The graft of the right lobe of the thyroid with its parathyroids was taken from a large monkey—a baboon—and implanted in the neck of the boy. It was embedded in a vascular region and was sutured closely to the surrounding tissues in order to promote adhesions and formation of new vessels. Voronoff states that during the six months since, the gradual improvement in both the physical and the mental condition has been striking. The boy had formerly been apathetic and stupid, the skin scaling off, the nose and lips enlarged; all this has retrogressed and the features show nothing abnormal while from his former apathy in school the boy has become lively and unruly.

31. Ascaris in Pyopneumothorax.—A robust country woman was taken suddenly with pains suggesting pleurisy and puncture later revealed fetid pus. After a purge she passed two ascarides. As the pyopneumothorax persisted in spite of treatment, the pleura was opened and a macerated ascaris was found in the pus. Recovery was soon complete showing that there could not have been a fistula at any point.

- 35 *Tardy Equivalents in Gastric Pathology. R. C. Augistrou.

35. Tardy Equivalents in Gastric Pathology.—Augistrou gives the details of 7 cases in which there were various disturbances coming on two or three hours after a meal, but not the usual train of pains relieved by vomiting, with the painful point in the back when food is ingested. Instead of this familiar syndrome, his patients had various disturbances which he regards as the recurring equivalents of the above syndrome. Five of them at this time after meals became dizzy and extremely depressed with tremor and profuse sweating, some feeling that death was impending. Two had besides recurring pain in the shoulder and arm or lower part of the chest. In only 2 of the 7 cases were the patients relieved by taking food, and one by vomiting. In only 2 cases was the stomach region tender during the acute phase. In 2 cases, however, there was a history of the typical tardy gastric pain in former years. In another case the atypical disturbances described above progressed to become finally the true typical attacks. One case was peculiarly instructive as the typical and atypical disturbances alternated, all coming on at the same hour after eating, the reflex pains and the general reaction at one time and another day the intense pain localized in the stomach.

Some of the patients had been treated for months in vain with drugs to act on the nerves and neuralgia, but a cure was soon complete when the diet was restricted to milk and egg dishes, with some alkaline powder. The gastric juice may be secreted in excess or there may be a deficit; the only reliable differential signs are the regularity of the interval after eating when the disturbances appear and their subsiding again; the regular recurrence for a few days to two

weeks or more, and the usually complete cure under the simplest dietetic measures. The trouble is not hyperchlorhydria but merely abnormal sensitiveness of the gastric mucosa or spasm of the pylorus in persons with an unstable nervous system. All the above patients were what he calls inveterate neuropaths, great talkers, easily moved to tears or anger, and often complaining of headache and not feeling well in the morning.

Journal d'Urologie, Paris

July 15, VI, No. 1, pp. 1-152

- 36 *Anuria from Relics of Old Pelvic Inflammation. (Des anuries de cause indéterminée.) P. Bazy.
- 37 *Reflux of Urine into Ureter; Four Cases. (Reflux urétéral acquis.) O. Pasteau.
- 38 *Suburethral Abscess in Women. (Abscess urinaire chez la femme.) P. Héresco and M. Cealic.
- 39 *Syphilitic Lesions in the Bladder. (Syphilis vésicale.) G. Gayet and Favre.
- 40 *Restoration of the Bladder. R. Grégoire.
- 41 *Modified Technic for Perineal Prostatectomy for Cancer. R. Proust.

36. Anuria from Indeterminate Cause.—Bazy reports several cases of anuria apparently ascribable to a calculus but nothing of the kind could be found, and the course of the cases showed that the trouble was some mechanical obstruction of the ureter, but not from stones, neoplasms or inflammatory processes. In the first case a man of 73 had had kidney colic and passed gravel at various times. The ureter evidently became dilated and stretched during the course of this nephrolithiasis, with the consequence that it became kinked low down and anuria resulted. Roentgenoscopy showed some vague shadows which suggested calculi in the pelvic ureter but which must have been of other origin. These misleading shadows were noticed also in two other cases of anuria in all of which concretions were incriminated but finally they had to be exculpated. Decapsulation of the kidney in one case started instantaneously the natural flow of urine. These "false calculi" are generally multiple and bilateral; the organs and soft parts in which they are located are movable, and hence the false calculi can be displaced in their relative positions. They are evidently relics of old inflammation in the pelvis and may drag on or kink the ureter in time.

37. Reflux of Urine into Ureter.—Pasteau does not refer to a congenital dilation of the ureter but to an acquired permanent gaping of the pathologic ureter mouth, or to a transient gaping. He describes a case of the latter in which an opaque fluid in the bladder was forced up into an apparently normal ureter between the spurts of urine from the ureter. The other ureter and kidney were tuberculous. After nephrectomy there was no further reflux in the other ureter, demonstrating that there had been no anatomic lesion but merely transient atony of the musculature. The danger is imminent of infection of the sound kidney from the reflux thus invited; it is further favored by the abnormally powerful contractions of the secondarily inflamed bladder. Another point to be borne in mind is the possibility of blundering in the diagnosis when from the ureter urine is drawn that came from the bladder instead of the kidney.

38. Suburethral Abscess in Women.—Héresco and Cealic report four cases of abscess on the median line just below the urethra in which the pus was mixed with urine, all the features of the suppuration corresponding to the analogous urinary fistulas in men.

39. Syphilis of the Bladder.—Gayet and Favre give a colored plate of the findings in three cases. The hematuric cystitis subsided so promptly under treatment for syphilis that there can be no question, they declare, of the specific nature of the bladder trouble. The hematuria came on suddenly and was profuse in each case, recurring, uninfluenced by local measures, at nearly every micturition, with more or less pain. The cystoscopic findings illustrated show various phases of syphilitic affections of the bladder. When they have progressed to ulceration, secondary infection blurs the clinical picture. The trouble usually is differentiated only by exclusion after the failure of ordinary measures.

40. **Restoration of Bladder.**—Grégoire thinks that the case he reports is the first to be published in which a new bladder was made from the rectum for extensive destruction of the vesicovaginal wall without exstrophy or cancer of the bladder. This is the fifth case in which this technic has been applied. Continence of urine was not secured in any instance but the results of the operation otherwise were satisfactory.

41. **Modified Perineal Prostatectomy.**—Proust's technic is profusely illustrated, featuring his method of locating the ureter where it crosses the vas deferens. Following the latter up to the seminal vesicles on each side, separating these from the bladder and turning them over backwards, exposes the region below so that access to the ureters is rendered simple by following along the vas on each side.

44 Convuluted Thickening of the Scalp. (Pachydermie vorticellée du cuir chevelu.) Malartic and Opin.

43. **Phthalein Test and Urea Excretion.**—Vidal, Weill and Radot state that with the phthalein test, the Ambard formula and tests for urea in the blood-serum, remarkably parallel findings were obtained with all. They list them from a number of cases, the figures all rising and falling together, both in normal persons and in patients with Bright's disease as also in patients with both heart and kidney disease but not oliguria. This parallelism confirms the precision of the various tests and favors the choice of the simplest technic which is that of the phthalein test. They remark in addition that this latter technic is free from the sources of error to which the others are liable. As it gives the same results as the Ambard formula they should be interpreted in the same way.

They distinguish between true azotemia, that is, retention from progressive accumulation of urea in the body fluids, and the azotemia which is merely the result of some disturbance in the excretion of urea which is borne for a long time without the urea accumulating in the body fluids. The fluctuating urea content of the blood serum in these cases is of no import for diagnosis or prognosis unless considered by means of the phthalein test or Ambard formula. This reveals the slightest upset in excretion of urea, and confirms the assumption of an underlying kidney lesion in case of incipient or abortive Bright's disease.

July 22, No. 29, pp. 337-348
56 *Signs of Organic Hemiplegia. J. Lhermitte.

55. **Chronic Appendicitis and Torsion of Omentum.**—Lejars relates a case which shows that adhesion and partial torsion of the omentum or even of one strand of fibers may entail symptoms suggesting chronic appendicitis. The omentum trouble is generally traceable to mischief in the appendix, possibly many years before. In his case twenty-two years had elapsed after a brief and mild attack of appendicitis, leaving chronic slight tenderness, when the man of 39 suddenly developed new symptoms and the operation revealed the omentum adherent to the nearly normal appendix, the stretched adherent strip twisted several times on itself. This and the few similar cases on record teach the importance of examining the omentum even to quite a distance at all appendix operations.

56. **Signs of Organic Hemiplegia.**—Lhermitte discusses the phenomena characteristic of organic hemiplegia to which Panski, Babinski and Bergmark have recently called attention. Even although we already have many signs of organic hemiplegia, yet these *symptomes de luxe* are important not only because they aid in excluding functional trouble but also because they throw light on the pathologic physiology of the syndrome. They show that ordinary hemiplegia is an infinitely more complex manifestation than was formerly recognized. Not only the apparatus innervated by the centers in the region injured suffer from the disturbance in the centers (deficit phenomena), but other apparatus connected with them suffer likewise, either from loss of control (in which case anarchy prevails among them), or from excessive control of inhibition (phenomena of dissociation or Monakow's diaschisis). Among the comparatively new signs revealing trouble of this kind is the excessive secretion of saliva; the heavy coating of the tongue, sometimes only on the paralyzed side, profuse excretion of urea crystals stopping short at the median line, and a modified sense of taste or smell on the paralyzed side. This may be bilateral, and it may explain the loss of appetite in some cases. The sphincters may act in an anarchistic way, and enuresis may be the only sign left of a transient, possibly scarcely noticed, hemiplegia. This anarchy of the sphincter may be exaggerated or brought back by changes in temperature, by sneezing or coughing. In one case irresistible micturition occurs every time the hemiplegic takes his place at the table. Panski has also reported recently three cases in which glycosuria disappeared after organic hemiplegia developed. One woman of 60 had 5 per cent. sugar in the urine before, but there was none afterward for a year, not even after subsidence of the hemiplegia, and it did not run above 2 per cent. at any time. In the others it never reappeared, or only at long intervals. Babinski applies the term *anosognosie* to a peculiar modification of the consciousness which he has noted in two cases, namely, the complete ignoring or the semblance of completely ignoring the fact of the hemiplegia. The patients seemed absolutely unaware of their infirmity although otherwise they were intelligent.

67. Section of Spinal Roots for Spastic Paralysis.—Gümbel has compiled 107 cases in which Foerster's operation has been done for Little's disease. The mortality was 13 per cent. He has operated himself in 8 cases, here described in detail. One patient died and the outcome was injuriously affected in one case by an intercurrent hip-joint disease. The results were disappointing in all; none of the patients is able to use his legs although painstaking after-care followed the operations. Better results are obtained in spastic paralysis with the ordinary measures. A still further drawback of the operation is that the laminectomy left a weakness of the spine. In one of his cases the tendency to curvature of the spine became much aggravated and in 2 others curvature developed in previously straight spines.

70. Disturbances Resulting from a Tendency to Atypical Gout.—The first part of Goldscheider's article was reviewed in these columns August 15, abstract 58, p. 613. He describes here a number of typical cases of atypical gout and allied metabolic disturbances all of which call for treatment similar to that for true, typical gout. The importance of the subject lies in the unrecognized or overlooked fact that a number of symptoms on the part of the nervous and circulatory systems and the kidneys are the result of metabolic disturbances analogous to or identical with those of gout. These may be due to an inherited tendency, to overwork, or to lack of exercise. Treatment of the metabolic disturbances applied in time and systematically is liable to give highly gratifying results. The groups of the atypical forms of gout include persons with a gritting noise in the joints, with or without tophi; obesity; congestion in the liver; kidney stones and gravel and nephritis. He found gout in 163 of 424 obese patients; the symptoms were much the same in all. Pains in the joints were more common in the obese with high blood-pressure. He found typical or atypical gout further in 30.1 per cent. of 232 cases of enlarged liver in the non-obese. In 4.9 per cent. there was a tendency to kidney stones, and among those with cardiovascular symptoms the proportion was 10 per cent.

It seems plausible to assume that symptoms on the part of the cardiovascular system, nerves, etc., in these cases are due to deranged or insufficient metabolism of purins or to excessive intake of purins beyond what can be properly metabolized, or to the inherited tendency underlying the constitutional obesity, or to an upset in the liver control of metabolism. Goldscheider's aim is to emphasize the importance of a deranged metabolism as a factor in cardiovascular, nervous and renal phenomena. He admits that the only proof he has to offer for some of his statements is the success of treatment based thereon.

71. The Thymus with Exophthalmic Goiter.—Matti's research and study of the literature confirm that the thymus is often directly concerned in the production of exophthalmic

goiter. The monopoly hitherto enjoyed by the thyroid is at an end. The adrenals often are insufficient in this disease and epinephrin may be indicated to prepare the patient for operative treatment. The changes in the thymus in exophthalmic goiter are not to compensate for the thyroid, but are directly coordinated with and parallel to the changes in the thyroid.

July 18, XLIV, No. 29, pp. 897-928

- 72 Atrophy of the Prostate. A. Müller.
- 73 Endemic Goiter. (Zum Kropfproblem.) E. Bircher.

72. Atrophy of the Prostate.—Müller remarks that comparatively few realize that retention of urine may be the consequence of atrophy of the prostate as well as of hypertrophy. An abnormally small prostate may cause a clinical picture in every respect similar to that from enlargement of the organ. It sometimes happens that the syndrome is ascribed to nervous incompetency of the bladder as the anticipated enlargement of the prostate is not discovered. He had two typical cases of the kind which he here describes in detail and compares with analogous experiences on record. The disturbances are caused not by obstruction from enlargement of the gland but from derangement of the functioning of the bladder sphincter which is involved more or less in the shriveling process. The suprapubic incision permits better oversight and is to be preferred in these cases. Differential diagnosis is difficult mainly in that all bladder disturbances of central origin, especially tabes, have to be excluded before positively incriminating atrophy of the prostate. In some cases hypertrophy of one part was accompanied by atrophy of the rest or there may be a true miniature hypertrophy. Stretching the prostate, or the Bottini operation, or resection of the sphincter may cure the trouble after failure of medical measures. He compares the various technics in vogue, especially Young's conservative operation, which he describes in detail, remarking that he does not know of its having been applied to date to any extent in Europe.

74. Threatening Conditions with Pneumothorax.—Grober does not refer to induced artificial pneumothorax but to that complicating tuberculous processes or stab wounds or other injury of the lungs, when it is important to relieve vital organs from the pressure of the air. The air must be allowed to escape only very slowly, through a puncture needle and tube into a jar of water. Dry cups may relieve pain for hours at a time, and the patient may become accustomed to his pneumothorax until it no longer distresses him. But during the acute phase opiates may be necessary. By relieving the pain they permit deeper breathing and this helps to restore the circulation. Swallowing may be impeded by the displacement of the esophagus, and special care with the food is necessary on this account. Signs of sepsis may render puncture advisable even when there are no symptoms

from compression. Heart stimulants may be usefully combined with the opiates in some cases.
